MANUFACTURERS

1. Acme Resin Corp., 1401 Circle Ave., Forest Park, Ill.
2. Acryvin Corp. of America, 470 E. 99th St., Brooklyn 36, N. Y.
3. Allied Resinous Products, Inc., 525 W. Adams St., Conneaut, Ohio
4. American Agile Corp., Maple Hgts., Ohio
5. American Alkyd Industries, Broad and 14th Sts., Carlstadt, N. J.
6. American Cyanamid Co., 30 Rockefeller Plaza, New York 20, N. Y.
7. American Hard Rubber Co., 93 Worth St., New York 13, N. Y.
8. American Insulator Corp., New Freedom, Pa.
9. American Lucoflex, Inc., 500 Fifth Ave., New York 36, N. Y.
10. American Molding Powder & Chemical Corp., 703 Bedford Ave., Brooklyn 6, N. Y.
11. American Plastics Corp., 342 Madison Ave., New York 17, N. Y.
12. American Reinforced Sales, 650 S. Spring St., Los Angeles 14, Calif.
13. Anchor Plastics Co., 36-36 36th St., Long Island City 6, N. Y.
14. Archer-Daniels-Midland Co., Chemical Products Div., 2191 W. 110th St., Cleveland 2, Ohio
15. Armstrong and Associates, C. W., Argonne Road, Warsaw, Ind.
16. Atlas Mineral Products Co., The, Mertztown, Pa.
17. Atlas Powder Co., Wilmington 99, Del.
18. Auburn Button Works, Inc., 48 Canoga St., Auburn, N. Y.
19. Bakelite Co., Div. of Union Carbide & Carbon Corp., 30 E. 42nd St., New York 17, N. Y.
20. Barrett Div., Allied Chemicals & Dye Corp., 40 Rector St., New York 6, N. Y.
21. Biggs Co., Inc., Carl H., 2255 Barry Ave., Los Angeles 64, Calif.
22. Borden Co., The, Chemical Div., 350 Madison Ave., New York 17, N. Y.
23. Borden Co., The, Chemical Div., Resinite Dept., Santa Barbara, Calif.
24. British Geon Ltd., London S. W. 1, England
25. British Resin Products Ltd., London S. W. 1, England
26. Cadillac Plastic and Chemical Co., 15111 Second Ave., Detroit 3, Mich.
27. Campco Div., Chicago Molded Products Corp., 2717 N. Normandy Ave., Chicago 35, Ill.
28. Canadian Industries Ltd., P.O. Box 10, Montreal, P.Q., Canada
29. Capac Industries, Inc., Capac, Mich.
30. Carboline Co., 331 Thornton Ave., St. Louis 19, Mo.
31. Cast Optics Corp., 123 Newman St., Hackensack, N. J.
32. Catalin Corp. of America, 1 Park Ave., New York 16, N. Y.
33. Celanese Corp. of America, Marco Products Dept., 290 Ferry St., Newark 5, N. J.
34. Chemical Coatings and Engineering Co., Inc., 2633 Westchester Pike, Broomall, Pa.
35. Chemore Corp., 21 West St., New York 6, N. Y.
36. Ciba Co., Inc., Plastics Div., Kimberton, Pa.
37. Coast Pro-Seal Mfg. Div., 1507 Grand Vista Ave., Los Angeles 23, Calif.
38. Columbia-Southern Chemical Corp., 1 Gateway Center, Pittsburgh 22, Pa.
39. Cordo Molding Products, Inc., 230 Park Ave., New York 17, N. Y.
40. Crane Packing Co., Teflon Products Div., 6400 Oakton St., Morton Grove, Ill.
41. Cutler-Hammer, Inc., 492 N. 12th St., Milwaukee 1, Wis.
42. Davis Plastics Co., Joseph, Arlington, N. J.
43. Dewey & Almy Chemical Co., 62 Whittemore Ave., Cambridge 40, Mass.
44. Dow Chemical Co., The, Midland, Mich.
45. Dow Corning Corp., Midland, Mich.
46. Du Pont de Nemours & Co., E.I., Wilmington 98, Del.
47. Durez Plastics Div., Hooker Electrochemical Co., 888 Walck Road, North Tonawanda, N. Y.
48. Eastman Chemical Products, Inc., Kingsport, Tenn.
49. Eastman Kodak Co., Rochester 4, N. Y.
50. Electronic Mechanics, Inc., Clifton, N. J.
51. Emerson and Cuming, Inc., Canton, Mass.
52. Epoxylite Corp., 10829 E. Central Ave., El Monte, Calif.
53. Fiberfil Corp., Warsaw, Ind.
54. Fiberite Corp., 516 W. Fourth St., Winona, Minn.
55. Firestone Plastics Co., P.O. Box 690, Pottstown, Pa.
56. Flexfirm Products, 2300 N. Chico Ave., El Monte, Calif.
57. Foster Grant Co., Inc., Petrochemical Div., 289 Main, N., Leominster, Mass.
58. Furane Plastics, Inc., 4516 Brazil St., Los Angeles 39, Calif.
59. Garfield Mfg. Co., 10 Midland Ave., Garfield, N. J.
60. Garlock Packing Co., The, Palmyra, N. Y.
61. General Aniline & Film Corp., Commercial Development Dept., 435 Hudson St., New York 14, N. Y.

HOW TO USE MODERN PLASTICS ENCYCLOPEDIA'S NEW PLASTICS PROPERTIES CHART

This revised Plastics Properties Chart is designed to make it easier for the user to find specific information.

Vertical columns represent properties; horizontal columns represent plastics materials. To facilitate the selection of materials having desired properties, bars have been drawn in to supplement numerical values. Each bar (which appears below the numerical value) relates to the scale appearing at the top of each vertical column. Thus, for example, the user who is seeking a material with a high tensile strength can simply scan the vertical columns representing Tensile Strength and visually determine by means of the bars which plastics material fall into the higher strength range.

Circles (as opposed to bars) indicate single values (as opposed to a range of values). Arrows indicate ranges in which the upper limit exceeds the scale range. Arrow heads indicate numerical values which also exceed the scale range, but in such instances even the lower limits do not fall within the scale range. Open-ended bars indicate values which are "more than" or "less than" a given range; the side on which the bars are open distinguishes between "more than" and "less than" (e.g. bars open to the right indicate "more than"; bars open to the left indicate "less than").

For users seeking complete property information on a specific material, the chart can easily be read horizontally. The last two columns of the chart give the manufacturers and trade designations of each plastic material.

with plasticizer.

This chart covers molding and extrusion compounds, cast resins, and sheet, rod, and tube stock. The values for the properties in the chart are based upon maximum and minimum figures submitted by a number of manufacturers of each type of plastic material. Differences in these procedures and sizes of test specimens may lead to erroneous conclusions in some cases if direct comparisons are attempted.

[b]The values reported for this property depend on the size and shape of the test piece and the molding conditions. The maximum permissible service temperature will vary with the formulation of the material, design of the part, and service conditions such as amount of stressing, humidity, etc. Requirements for resistance to heat should be considered a special problem.

ast resins, and sheet, rod, and tube stock. The imum and minimum figures submitted by a number ces in these procedures and sizes of test speci- irect comparisons are attempted.

Special gra should always the producers of plastics are with materials

[4]Surface resistivity decreases.
[5]Loss in surface ductility.
[6]In high concentration.
[7]Resists aliphatics; soluble in ketones, aromatic
[8]Resists aliphatic hydrocarbons and most oils; and aromatic hydrocarbons; dissolves in alcohols.
[9]Slightly soluble in ethylene dichloride and some solvents.
[10]Soluble in ketones, esters, and some chlorinated
[11]Variable. Attacked by ketones, esters, some ha
[12]Halogenated compounds cause slight swelling.

Special grades of materials are often available that excel in one particular property. The manufacturers should always be consulted before making a choice of material. In order to facilitate communications with the producers of these materials, the names and addresses of manufacturers of each of these chemical types of plastics are listed in the chart. Complete street addresses will be found in the Directory Section. Check with materials suppliers for type of filler desired.

[a] Code for compatibility: C = compatible, P = partially compatible, I = incompatible. [b] See list on page 614 for key to numbers.
[c] Measurement made at 20 °C. [d] The trade marks for plasticizers are shown in quotation marks.
[e] Decomposes at temperatures in this range.

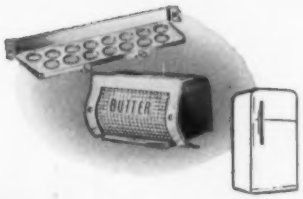
Our TWO modern plants will *Efficiently*.....

1. ELYRIA, OHIO

In which is located General Industries' engineering and mold-making departments together with its extensive facilities for compression and transfer molding of thermosetting materials.

facilities



- **COMPLETE ENGINEERING SERVICE**
  Capable engineers, qualified by years of experience, to see that your designs are produced at lowest possible unit molding cost.
- **COMPRESSION MOLDING**
  180 various compression and transfer presses, most with top rams, ranging from 25 - ton to 1850 - ton capacity.
- **INJECTION MOLDING**
  16 modern injection molding presses ranging in size from 2 oz. to 200 oz. capacity for low cost, efficient production of thermoplastic materials of the highest quality in any quantity.
- **RADIO-FREQUENCY PREHEATING**
  One of the largest installations in the industry . . . more than 75 separate units to facilitate high-speed molding production.
- **CONVEYORIZED OPERATION**
  From press to shipping room, through finishing and assembly operations, entire operation conveyorized for fast, uninterrupted flow of molded parts.
- **FINISHING EQUIPMENT**
  Automatic facilities include equipment for trimming, polishing, buffing, drilling, tapping, tumbling and painting.

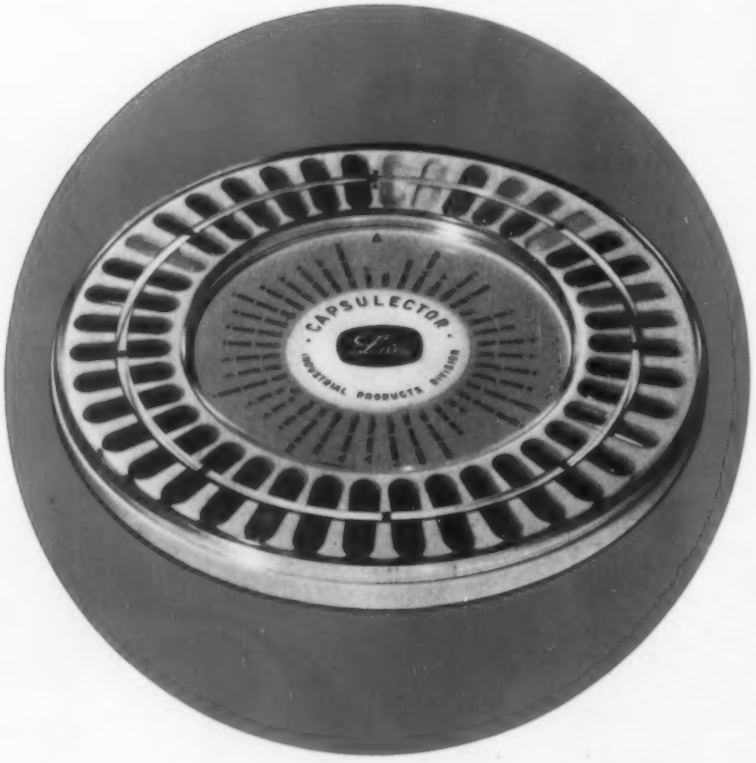
experience

• Over the years, General Industries has engaged in the engineering and production of custom-molded plastics for many of America's largest manufacturers.

• Included among General Industries' current customers are the largest manufacturers of refrigerators and appliances, cooking utensils, telephones, cameras, textile machinery, automobiles and many other products.



• Write or phone today for the services of our experienced Sales Engineers who will be happy to call on you and assist you with your engineering design and answer questions on your technical problems. General Industries will also conduct a survey at no cost to you of your product and advise you if you now have an item that can be made better and at a cost savings to you through conversion to the proper plastic material.

THE GENERAL INDUSTRIES CO.

Department PL • Elyria, Ohio

it is no secret–

Standard Molding Corporation products are the finest that can be obtained in the field of thermoplastic molding —however, fine production is just one of the many services offered by SMC of Dayton.

ideas–

Just an idea is all that is necessary to start SMC thermoplastic engineers and production experts working on your specific problem.

facilities–

SMC is equipped to handle any job which falls within the scope of thermoplastic molding—it is staffed to meet design and production schedules.

result–

Your ideas take form and become gratifying realities in a minimum of time—it is no wonder, then, that the Eli Lilly & Company of Indianapolis, Indiana, after having had previous satisfactory production experience with SMC, again turned to us for the development and production of the CAPSULECTOR, colorfully shown in the accompanying illustration.

let's review what happened–

Eli Lilly & Company sells empty gelatin capsules to other pharmaceutical companies—their packaging department needed a case to display their line of capsules, both in solid colors and in all the possible combinations of colors.

The idea for this case, along with some rough sketches, was presented to SMC early in the Spring of 1956. Immediately, SMC Engineers, in conjunction with representatives of the Lilly Packaging Development Department, started processing of designs and sketches which were accepted in July.

Two molds were begun, one for the inner and outer white parts and one for the clear part. By October of the same year, 1956, the tools had been sampled and the molded parts approved—production followed immediately.

Standard Molding Corporation is proud of this production achievement —is proud of the quality of the product and is proud of the trust that the Eli Lilly & Company places in our ability to create and produce the finest in thermoplastic molded products.

The solution of your problem may lie within the field of thermoplastics— You are invited to consult with our Engineers who will be glad to advise you concerning the potential of thermoplastics in relation to your needs.

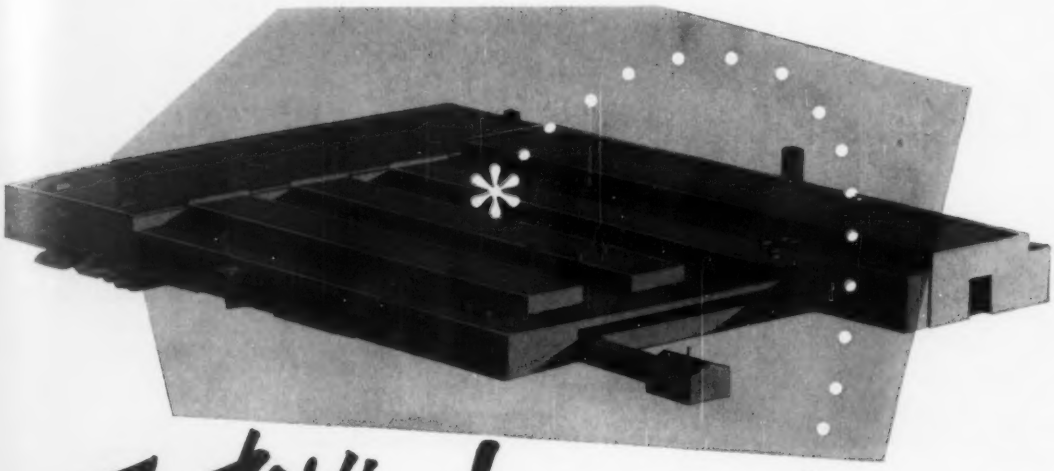
WHAT A DIFFERENCE THE MOLD MAKES!...

A Perfect Reflection of Mold Polishing and Skill by Precision

Skill and experience make Precision's method of mirror-finished mold polishing second to none in the industry. Minute details are reproduced to meet the strictest specifications. All drafts and tapers are carefully checked to insure proper radii. Our proven procedures assure better cycles, more efficient mold operation and molded parts of superior finish.



Why continue to wrestle with costly problems resulting from molds of inferior finish. Submit your specifications for quotations on mirror-sheen finishing for existing or contemplated molds. You'll find our charges reasonable and service prompt. Satisfaction guaranteed.

"I Prefer to Have My Plastic Products Custom Molded by Ideal because..."

Here's how some of our customers completed this statement in twenty-five words or less:

RADIO MANUFACTURER

". . . Ideal's delivery of finished cabinets always is closely coordinated with our own production schedule."

REFRIGERATOR MANUFACTURER

". . . I find that Ideal gives us the realistic prices we seek without making any compromise on quality."

HOUSEWARES MANUFACTURER

". . . we frequently double or triple our orders to keep up with the changing market picture and Ideal has facilities to handle the production we want."

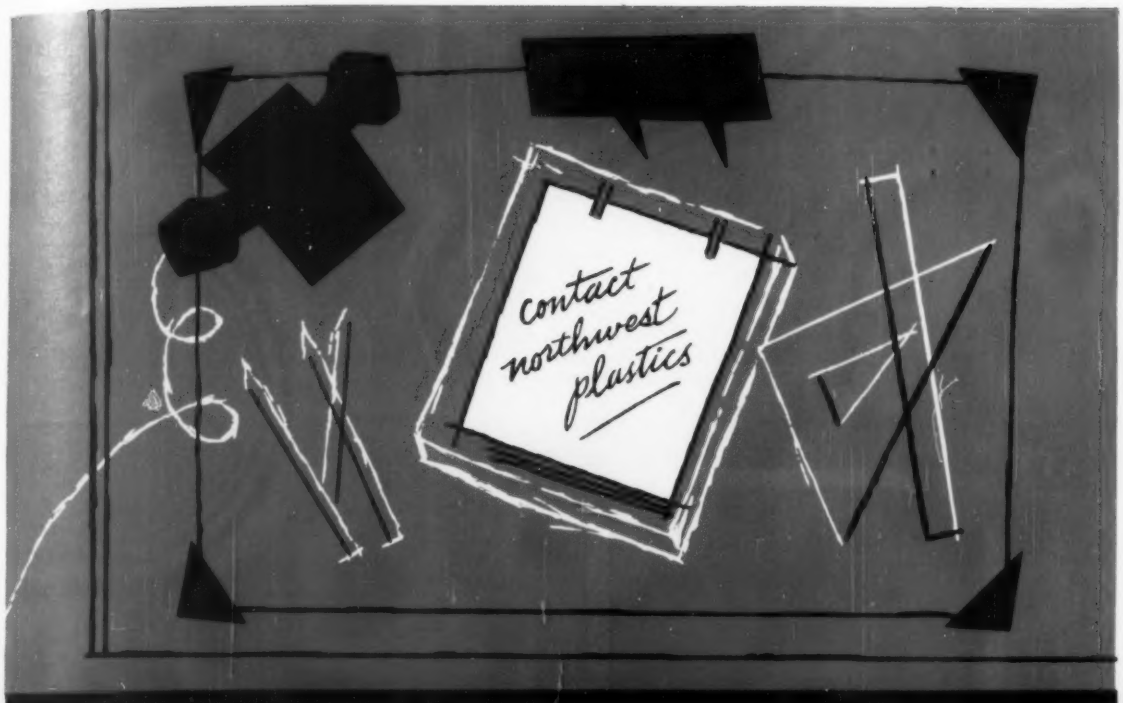
PREMIUM SPECIALTY HOUSE

". . . we have our product boxed at the molding plant and drop shipped, so we've got to rely on the honesty of our molder's inspection."

HOUSEWARES MANUFACTURER

". . . we depend on our molder to help choose the material for each of our products, and Ideal has given us wonderful help."

ADVERTISING NOVELTY COMPANY



". . . they do a splendid job of assembling, painting, and decorating the many gadgets and signs we purchase."

Men who make the products and pay the bills appreciate the value of placing their custom injection molding in the competent hands of Ideal Plastics. Our reputation has been firmly established on thousands of satisfactory molding jobs.

Ideal's facilities for mold design and building, production control, molding, and assembling are second to none. For a prompt estimate, contact A. C. Manovill, Vice-President in Charge of Sales. Ideal Plastics, 184-10 Jamaica Avenue, Hollis 23, N. Y. Phone: AXtel 7-7000.

Engelking's ABC of fine

Matched Metal Dies for Reinforced Plastics

Nothing approaches matched metal dies for rapid, precise, economical production of reinforced plastics. In the few short years of reinforced plastics molding, Engelking Patterns has made literally hundreds of sets of these dies for leading companies in all fields of endeavor.

The making of matched metal dies is a logical extension of Engelking's exacting wood pattern service. Starting from prints or drawings, Engelking performs every necessary step of die production in one of the Midwest's largest, best equipped pattern making and metal die making establishments. Key production equipment includes two Keller Duplicators, a BG-21 (6′ x 4′) and a BG-1 (5′ x 3′).

Write today for "The Story of Engelking" which explains our services in detail.

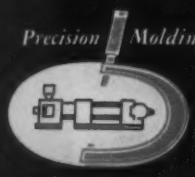
STEP 'A'

Making the Master Wood Pattern. Working from detailed blueprints, one of Engelking's master pattern makers transforms their flat instructions into an accurate 3-dimensional mahogany pattern. This premold mock-up has a dual purpose: it permits esthetic and engineering design analysis far more exacting than possible from prints alone, and it serves as the master for the Keller model.

STEP 'B'

Preparing the Keller Model. Shown here is half of a set of precise Keller models (one male, one female) made from the carefully finished wood pattern. Engelking prepares the models by building up over the pattern with a combination of glass cloth and special epoxy resin. When cured, these models act as "copy" for the Keller.

STEP 'C'



Kellering the Mold. The male epoxy-glass model is shown mounted on Engelking's 6′ x 4′ Keller where it is automatically traced and reproduced, contour for contour, in tool steel. A fine hand finishing operation readies it and its mate for molding. In this instance the reinforced plastics product is the housing for a popular outboard motor.

When the Twenties were roaring . . .

there were flappers, vamps, and "Oh, you kid," raccoon coats, the Model T, and "Twenty-three skiddoo." There was also a company named Boonton, custom molding plastics over in Jersey.

Now it's plastics that's roaring, and the fads of the Twenties have pretty much skiddooed. But Boonton's still custom molding plastics over in Jersey.

By this time, though, we've become pretty big in the industry—with an entire plant for compression molding, another for injection molding, still another for Boontonware (that's our famous line of molded dinnerware), and facilities for designing, finishing, assembling, and hot stamping.

We've also added a Special Products Division, as well. This division is set up to handle all the problems that require special ingenuity to solve. It might be the design and production of a piece for an unusual application, or one that doesn't lend itself to standard compression and injection methods. We use such techniques as casting . . . potting . . . low pressure molding . . . dipping . . . and electronic assembly. All this, of course, in addition to our regular compression and injection molding service.

As you can see, we can handle just about any job. Yours too, probably. So get in touch with us, won't you? You don't even have to knock three times and whisper, "Joe sent me." Write . . . wire . . . phone . . . or shout—if you're close enough.

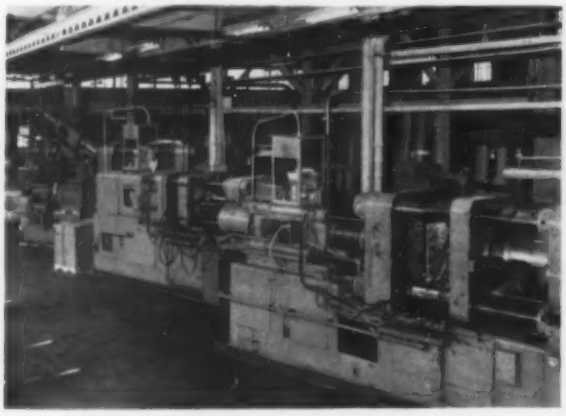
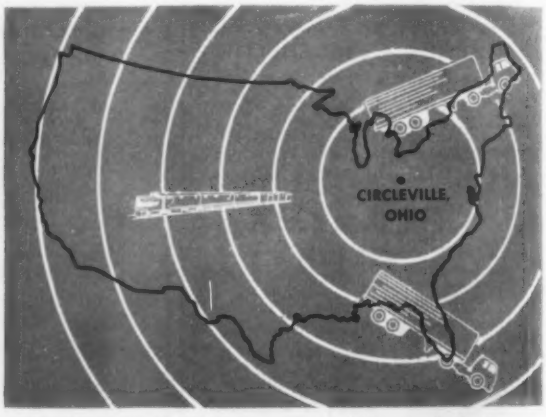
CUSTOM MOULDERS

LARGE OR SMALL CASTINGS

SPECIFY Lincoln MOLDED PLASTICS TODAY



. . . FOR YOUR PRODUCTS OF TOMORROW



WIDE RANGE OF EXPERIENCE– Lincoln Molded Plastics, Inc. has a wide range of experience in designing, engineering and producing a large variety of "Tomorrow-styled" thermoplastic products and components. Lincoln produces crisper drawers, escutcheons, inside freezer doors, radio cabinets, air conditioner parts and other ornamental items for 9 of the top 11 appliance manufacturers, as well as many other types of products for numerous other manufacturers.

TECHNICAL "KNOW-HOW"– Lincoln's experienced staff of designers and engineers have the technical "know-how" to develop designs, from your first inspiration through the finished product. Or we can take over at any phase in the development of your design and carry it to completion. Our engineering field service saves you time, and your inquiries are handled accurately and promptly.

COMPLETE FACILITIES– Lincoln's injection molding and vacuum-forming extrusion facilities are modern up-to-the-minute, and complete. Our quality control system requires close adherence to rigid standards, which insures you plastic components of the finest quality.

PROMPT DELIVERY– You get prompt delivery of plastic components anywhere in the Nation; first, because of our large and complete facilities we are able to provide fast service and second, because we are ideally located in the industrial heart of the nation.

If you're looking for a *reliable* source of supply, with design know-how and a wide range of experience in the thermoplastics field, to engineer and produce a variety of thermoplastic components for new or restyled products, check Lincoln Molded Plastics, Inc. WRITE TODAY for "Development and Progress" a FREE catalog fully describing the facilities of Lincoln Molded Plastics, Inc., Circleville, Ohio.

Lincoln helps you create and produce more of tomorrow today.

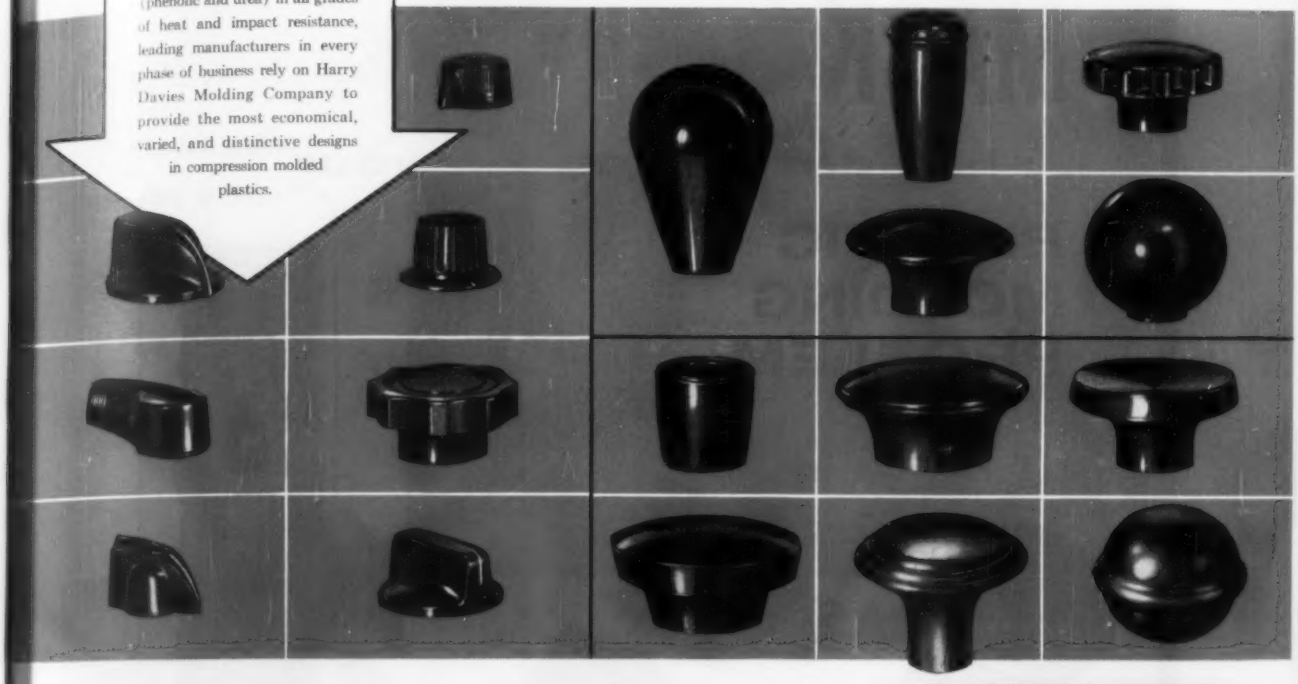
. . water pump impeller A special moisture resistant phenolic was specified for this part which must withstand the extremes of both high heat and intense cold, as well as strong torque action plus corrosion and cavitation resulting from the circulation of water in the car's cooling system.

. . timing gear The molded blank of this gear had to have high flexural characteristics . . also a good bond in the laminate section for ease in cutting gear teeth, and to insure necessary tooth strength. The manufacturer and Richardson developed a new material with high heat resistance. Result: Fine flexural strength in the web section . . more quiet operation . . . easier fabrication . . . easier assembly . . . *tripled gear life!*

. . radio antenna mast base This part had to have good surface appearance, high impact strength, high dielectric strength, and at the same time be weather resistant. A black phenolic material with an attractive high gloss finish was recommended.



. . dashboard light lens Originally this part was designed as a clear lens. Later, when the specifications were changed to call for a translucent lens, the customer suggested that either the mold, or the clear parts, be sandblasted. . either process would have increased costs. Richardson suggested, instead, a special light-transmitting polystyrene. Result: 15% reduction in lens cost.

More than 3500 variations of 275 Stock Mold Parts

MAKE YOUR PRODUCT DISTINCTIVE *at no extra cost*

For diversity in standard parts of thermosetting materials (phenolic and urea) in all grades of heat and impact resistance, leading manufacturers in every phase of business rely on Harry Davies Molding Company to provide the most economical, varied, and distinctive designs in compression molded plastics.

plus **25 YEARS EXPERIENCE IN CUSTOM MOLDING**

to the most exacting specifications

To the individual efforts of our experienced engineers and tool makers in successfully producing the most complex custom molds, the Harry Davies Molding Company adds superior production facilities, ultra-high speed machinery, and unlimited know-how in the field of thermosetting plastic materials.

You Can Save Thousands of Dollars By Use of These Combined Facilities

Looking for an injection molder

with experience on a wide range of products?

Leaf Plastics has produced just about every type of injection molding for some of the largest users of plastics.

We've accumulated considerable experience turning out molding for INDUSTRIAL, COMMERCIAL and MILITARY applications.

In addition to our injection molding facilities, we're set up for

- FINISHING
- ASSEMBLY
- DECORATING
- PACKAGING

Consult our technical staff on your injection molding needs. Simply send us a sketch or print of the required part, and we'll give you a detailed estimate, without obligation, of course.

Investigate the packaging field—

IT'S A BIG MARKET FOR PLASTICS!

"Big Market," is right! The men who select the materials used to package the output of America's biggest industries control a market that will hit the 15 billion dollar mark this year.

Typical of the 45 industries that comprise this rich market are companies which manufacture and package foods, cosmetics, chemicals, drugs, candies and tobacco products. In all these highly competitive industries frequent packaging changes are the order of the day. Factors ranging from fascinating sales appeal to plain hard costs influence the men who make the packaging decisions. Consequently, no one type of packaging material (glass, metal, paper or fabric) ever has assurance that it won't be supplanted by another.

And now plastics have entered the arena as directly competitive materials for packaging. In just the last few years they have come to play an increasingly important role—and often at the expense of older, "traditional" materials.

Especially noteworthy is the fact that plastics can be used in the manufacture of almost every basic package type: box, bag, bottle, drum, jar, vial or collapsible tube!

Right now this frontal invasion of the packaging field by alert plastics manufacturers, molders, laminators and fabricators has just begun. And their chief sales tools are the two publications which reach the men who make packaging decisions in all 45 industries—MODERN PACKAGING magazine, issued monthly, and the annual MODERN PACKAGING ENCYCLOPEDIA ISSUE.

Free Details about the Market

Additional data on using these media to help expand your sales to the packaging market are contained in the booklet "The Packaging Field—and how to reach it." Write for your free copy.

FAST FACTS ABOUT Mold Polishing

FACT A

Once you experience the speed and economy of Micron polishing, you will know it rarely pays to tie up your own expensive moldmakers on time-consuming mold polishing operations.

FACT B

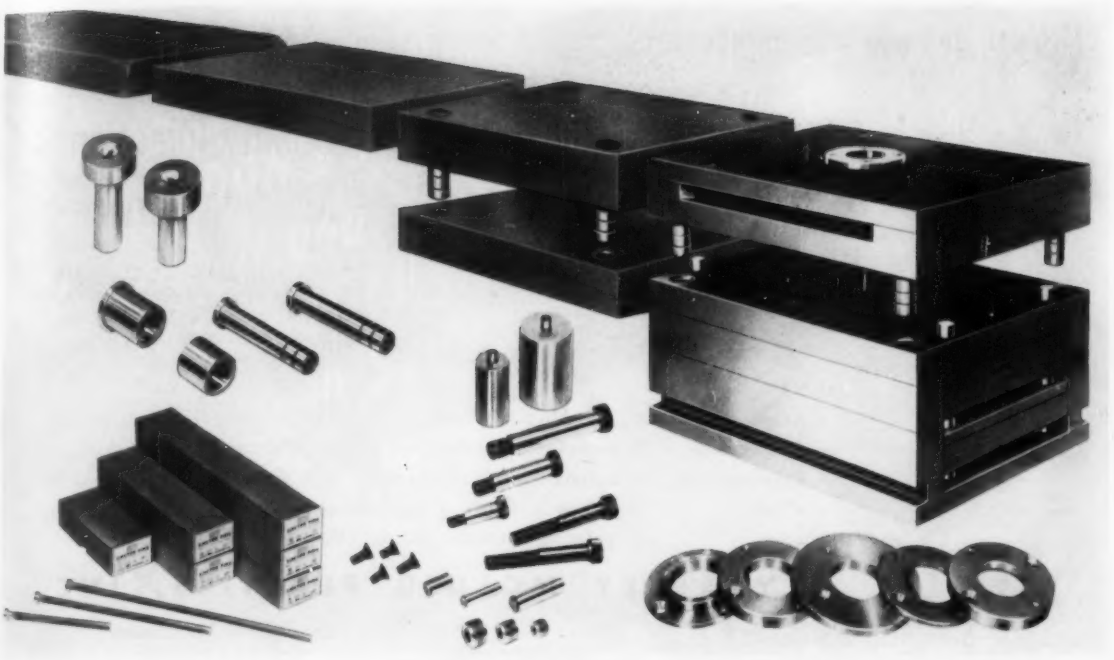
Fine custom mold polishing by a specialist — like Micron — costs less and takes less time than doing the same job in your own shop.

FACT C

Micron polishing does more than hide defects and blemishes... it actually removes them. Molds mirror-finished by Micron produce

- faster cycles
- excellent surface finish
- highest optical properties for transparent parts

Molds chrome plated, as required, to preserve finish during long runs.



FACT D

Micron mold polishing craftsmanship is employed by critical molders and moldmakers in all parts of the country. Micron speed, economy and results are unsurpassed.

Quotations furnished from blueprints or sample shots.

A full line of polishing supplies and diamond compounds.

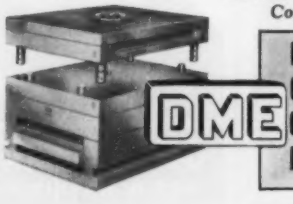
PROGRESS THROUGH STANDARDS

. . . and how DME "helped"

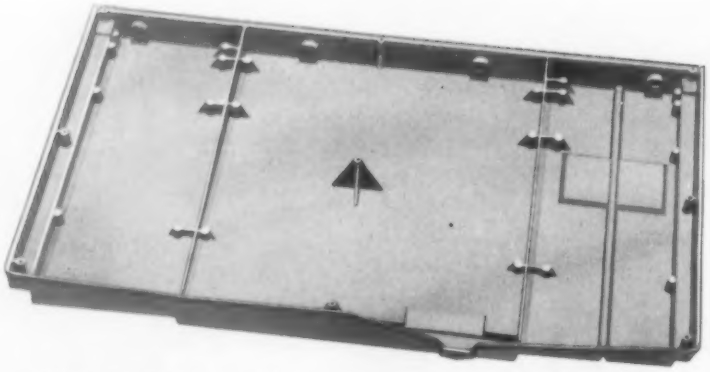
The history of economy in modern business has been directly related to the history of Standardization. One of the major elements affecting the economic production of finished plastic parts is the high initial cost of the mold. A progressive step in reducing mold cost, without sacrificing the high quality required, has been successfully achieved through Standardization.



When D-M-E originated Standard Mold Bases and their component parts in 1942, it provided the answer to the rapidly growing demand for high quality molds that would maintain and promote the economic advantages of plastic parts.

Through large volume purchases of quality steel in standard sizes and specialized production facilities, D-M-E was able to produce and supply high quality Standard Mold Bases to mold makers and molders at such great savings in cost and time that the benefits of Standardization were quickly realized by the Industry.

Today D-M-E produces twenty-eight different sizes of Standard Mold Bases, from 9" x 8" to 23¾" x 35½", in either D-M-E No. 1 or No. 2 Steel, with a wide range of cavity plate thicknesses to satisfy the diversified demands required. In addition, over 2,000 finished component parts of the same high quality are available to provide additional savings in service as well as in the product.



Properly engineered Standardization puts the accent on Economy. When you "Specify D-M-E . . ." you get Quality, Service AND Economy!

AICO . . . SUPER MARKET FOR MOLDED PLASTIC PARTS

Production in Depth

Assures On-Time Delivery of Your

Custom Molded Plastics

This new 20 oz. injection press, backed up by the big 48 oz. press, is typical of Aico's unusual Production in Depth. With press sizes from 1½ to 48 ozs., Aico's Injection Molding Department is equipped with several presses for practically every injection molding job. This correlation of Aico facilities assures on-time delivery for all your molded plastic parts.

At AICO, under one roof, you will find complete facilities for the economical and on-schedule production of all your custom molded plastics. Regardless of molding material, molding method used or quantities involved . . . production schedules are maintained by Aico's Production In Depth. At Aico, your job can be molded on more than one of the many presses in each Aico department. This is typical of Aico's complete plastics molding service that has provided many of America's leading manufacturers with product improvement, quality refinement and reduction of costs through the proper application of molded plastics.

CUSTOM COMPRESSION MOLDING

. . . . . our first product is Quality

Shown above are several different parts molded by KUHN and JACOB.

It's our job to custom-mold plastic parts of the highest quality that exactly fit their functional requirements. Every job, whether we start from scratch or follow customers' prints, goes through our engineering department. It is here that Kuhn and Jacob combines the benefits of many years of practical tool and die making with technical knowledge . . . often suggesting a change in design that may mean better performance in service, lower cost, faster delivery or other advantages to the customer. Not only in the plans stage and at the drafting board but through each succeeding manufacturing operation, Kuhn and Jacob engineers assume the responsibility for meeting customers' specifications—and for insuring the high quality and fine appearance of the finished piece.

Injection molding is a process that converts small pellets of thermoplastic resins, called molding powders, into shaped articles ranging in weight from 0.0002-oz. washers to 15-lb. battery cases.

Since most injection machines are made to work with molds that part along a single plane when opening, the articles to be made must be designed to be conveniently ejected from such molds. However, more complex shapes with undercuts, side projections, etc., have been molded by designing special molds with multi-surface parting and automatically retracting plugs. Metal inserts that are not too large can be molded into the article by positioning them in the empty mold cavity before injecting the plastic.

Basically, the process consists of five steps: 1) feeding the molding powder; 2) melting the feed; 3) injecting the melt into the relatively cool mold; 4) chilling the molding sufficiently below its softening range so that it will hold its shape when ejected; and 5) ejecting the piece. On some jobs, this process is supplemented by preheating of the feed and/or annealing of the ejected pieces.

General operation

Figure 1, p. 652, is a sketch of the longitudinal cross-section of an injection molding machine. The pellets — usually cubes, spheres, or stubby cylinders— drop from the hopper into the injection cylinder when the ram is retracted, filling the empty space. On the injection stroke the ram comes forward rapidly, forcing the pellets into the heated part of the cylinder and compacting them around the torpedo, or spreader. Fins along the torpedo keep it centered in the cylinder and conduct heat to it from the electrically heated cylinder wall. In this manner, a thin layer of the particles is heated by both the torpedo and the cylinder. In some machines, separate cartridge heaters are installed in the torpedo. Each successive stroke of the ram forces them further left until finally the material in the melt zone is forced out of the cylinder into the mold. Normally, there will be several cavities in the mold; the melt entering the center of the mold through the sprue reaches the cavities via small channels called runners. The part of the runner immediately adjacent to the mold is called the gate. Usually, this gate will have a much smaller cross-section than the runner, but there are cases where they may be about the same size, or, as with the acrylics, may sometimes be even larger than the runner. The melt in the cavities loses heat to the cold metal of the mold and freezes, starting at the outside surfaces. When a sufficient thickness has frozen, the mold opens and ejector, or knockout, pins poke the pieces out of the cavities. The mold is closed and the entire cycle is repeated. Although some molding machines are referred to as continuous, the process is clearly an intermittent rather than a continuous one. Equilibrium in the usual engineering sense is never achieved anywhere in the machine. This intermittency, of course, serves to complicate the

detailed analysis of what is happening to the material inside the machine.

Although the injection molding process ends with ejection of the piece from the filled mold, understanding begins there. We are accustomed to thinking of gases as being compressible, liquids and nonporous solids as incompressible. Plastics melts, however, probably because of their spongy molecular structure, exhibit considerable compressibility and have large coefficients of thermal expansion. Under the large changes in pressure and temperature encountered in injection molding, these characteristics result in considerable changes in density. The equation-of-state concept, so successful with gases, also works with plastics melts (40).[1] The fundamental notion is this: the density of a nonmoving plastics melt is fixed by its pressure and temperature. With some modification, the idea is also valid for plastics in the solid phase; the usual recognition of the effects of phase changes must be made, and, because some plastics may reach equilibrium density rather slowly at low temperatures, the rate of cooling or heating may be a significant factor.

The densities of most plastics at room temperature and one atmosphere pressure are highly reproducible, and it is known that, given a little time, a molded plastics object will return after molding to this density, known as the "standard density." If the equation relating density to pressure and temperature is known, it is simple to calculate what the weight of a piece made in a mold of given volume will be. From this weight and the standard density, its volume at room temperature and its approximate dimensions can be calculated. Thus, the equation-of-state is a tool for estimating molding shrinkage and calculating the effects on piece dimensions of changes in molding conditions. The idea, along with some data and calculations, is discussed at length in Reference 39. Here we can sum it up by noting that density increases as pressure is increased or as temperature is decreased, the temperature effect being much the larger. Thus, raising the injection pressure results in cramming more matter into the mold cavity (this is *not* due to stretching of the cavity—since it is usually made of thick, stiff steel, that stretches negligibly at the pressures involved); when this heavier piece is ejected from the mold at atmospheric pressure, it decompresses to a larger volume than would a piece molded at a lower pressure. Similarly, the higher the molding temperature, the greater the subsequent contraction when the piece is chilled to room temperature. This basic behavior pattern explains why melt pressure at the nozzle must be closely controlled if close dimensional tolerances are to be held on the plastics pieces which are to be molded.

[1] Numbers in parentheses link with References on p. 655.

Feeding

The direct feeding method shown in Fig. 1, p. 652, where the plastic pellets fall directly from the hopper into the heating cylinder, depends for its regularity on the fact that the ram retracts to the same point before each feed stroke. Presumably, then, the same volume is refilled on each cycle, giving rise to the term "volumetric feeding." In practice, however, the method has resulted in variations in shot weight and piece dimensions, and in flash on large-area pieces. Flash occurs when the mold opens slightly and some melt "flashes" into the parting crack, leaving an unwanted fringe around the piece. These variations can be traced to variations in pressure at the nozzle, which in turn are due mostly to variations in the weight of material fed. (19). Because the orientation of loosely falling cubes is not the same from shot to shot, the *weight* fed by the "volumetric" method can vary over a wide range, particularly in the smaller machines. An extra-heavy shot results, on the next shot, in there being a thicker-than-usual bed of solid particles through which the ram pressure must be transmitted to the melt. Since the ram pressure is set at a fixed value, the pressure at the nozzle drops, causing "short shots" (cavities only partly filled) or reduced weight and dimensions even when the cavity appears to be filled.

Improved regularity of feeding is accomplished by two methods, the weigh-feeder and the vibratory feeder. A weigh-feeder, as its name indicates, weighs the shot out from a secondary hopper and drops it into the injection cylinder. In reasonably sized shots, say 2 oz. and up, the precision of feeding depends only on the precision of the scale, and excellent scales have been adapted to this purpose. The vibratory feeder consists of a hopper supplying a magnetically vibrated trough, and a timer that regulates the interval of vibration. With cubes, in particular, precision is good—on the order of $\pm$ 1 percent.

Precision feeding does not completely solve the problem of shot-to-shot uniformity of pressure at the nozzle, since the unmelted particles in the cylinder cannot be relied upon to pack in the same way on each stroke. Bridging of the solid particles is especially important when the machine is operating close to its plasticating capacity, i.e., the maximum rate at which it can produce melted plastic, because in this condition there is a large volume of unmelted solids in the cylinder.

Recently a more direct approach to getting uniform nozzle pressures has been introduced. It consists simply of measuring the nozzle pressure and using the measurement to control the ram pressure. Variations due to irregular feed or bridging in the cylinder are thus compensated by changes in ram pressure.[2] This method should find increasing acceptance among molders who must meet close dimensional tolerances on their output.

A third method of reducing shot-to-shot variability in moldings is to have no solids at all in the injection cylinder. Instead, melting is accomplished in an auxiliary chamber called a preplasticator and the melt is transferred to the injection cylinder before the injection stroke. This guarantees as good uniformity of

[2] Two different devices for controlling nozzle pressure were offered to the public during 1956, but only one has been adapted to all makes of molding machines. It is available from West Instrument Corp., Chicago, Ill.

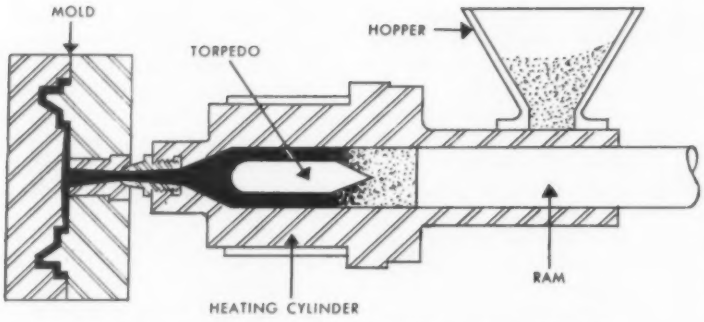

Fig. 1: Longitudinal cross-section of injection molding machine. Pellets of resin feeding from hopper are melted in the heating cylinder and forced forward by the ram into the mold where the melt is cooled and solidified

pressure at the nozzle as can be achieved in the hydraulic system driving the ram. Preplastication will be further discussed below.

Melting the feed

An injection machine is usually rated by the amount of general-purpose polystyrene it can deliver in a single shot. An equally important criterion is the plasticating capacity of the machine (31, 33). Although no standard has been set up to measure this capacity, it can loosely be thought of as the number of pounds per hour of cold molding powder that the heating cylinder is capable of melting. Obviously, this will be different for different resins and will depend on the melt temperature desired. Since higher temperatures are required for filling thin, large-area sections than thick, blocky ones, the plasticating capacity, in a practical sense, will depend on the job being done. However, it also depends on the design of the heating cylinder (27, 18, 16, 12, 13). All plastics are poor conductors of heat; yet even in the melt phase, because they are so viscous, they must be heated by conduction rather than convection or radiation. (Even in sheet forming, where radiant heat sources are used to heat the sheets, the heat is *conducted* into the interior.) It is therefore essential, for fast heating, to use the highest possible temperature gradients and the thinnest possible layers of plastic. Unfortunately, heating temperatures are severely limited by the rate of decomposition of the plastic. Even small percentages of decomposed resin may seriously impair strength, toughness, color, and surface finish of the pieces. In the melt zone of the cylinder, some material is in actual contact with the cylinder wall and because of the layer-like nature of viscous flow, material close to the wall moves very slowly. *Thus, if the wall temperature is above that level at which the material is decomposed significantly in a 20-min. interval, the molded product will inevitably contain a certain percentage of inferior material.* Because it is so easy to boost cylinder temperatures when increased plasticating capacity is needed, this unpalatable fact was accepted by molders only after it was decisively proved by molding many defective pieces.

The trend of heating cylinder design, therefore, has been directed at: 1) increasing the area of contact between plastic and metal, and 2) reducing the thickness of the heated layer. Both these aims have led to larger cylinders and larger torpedoes with reduced space between the two. One maker of replacement cylinders[3] has achieved multiple increases in heating capacity with reduced thermal hazard by abandoning the torpedo concept entirely. His cylinders are simply solid hunks of steel with many longitudinal circular holes drilled in them (16). Since the steel temperature is almost uniform throughout the block, heat pours into the plastic from all of the cylindrical surfaces of the holes.

Relatively recently, (12, 13) two similar designs were introduced. In both of these the standard torpedo is replaced by a perforated, grooved insert. The plastic pellets are forced against its inside surface and are partly melted until they can enter the perforations. Melting continues as they pass through the holes and grooves. On the stroke of the ram, the newly melted layer is skimmed off and forced out the nozzle and into the mold, while new pellets are forced against the liner surface. Advantages claimed for these designs are: greater plasticating rates, more uniform melt temperature, reduced thermal hazard, and better transmission of ram pressure.

Most cylinders are heated by band heaters wrapped around their outside surface. Because the added bulk of insulation is objectionable, most of these heaters are exposed to the air or covered with very thin insulation. As a result, more of their heat is lost to the surroundings than goes into the plastic. Future cylinder designs will probably tend toward more efficient use of heat.

The plasticating capacity of a given heating cylinder can be estimated from its dimensions and the thermal properties of the plastic to be molded. Some data on such properties are available from material suppliers.

The equations of heat conduction, integrated for heating long slabs or rods, may be used. Handy solutions of these equations were presented in graphical form by Gurney and Lurie (41) and they are reproduced in many books dealing with heat transmission (39a).

Pressure drop in the cylinder may be estimated from a formula presented in Reference 38. A recent extension of this work to include the effects of lubricants was reported in 1956 (10).

Injection

During the injection stroke the melt is forced at high rates of flow through the nozzle, sprue, runners, and gates into the mold cavities. While the problem of computing flow rates of hot melts under molding machine conditions is still under consideration, much has been learned about their flow

[3] Injection Molders Supply Co., Cleveland, Ohio.

behavior in the laboratory (23, for example). This knowledge serves as a guide in designing runners and gates. For example, it is known that polymer melts are non-Newtonian, i.e., they do not obey Newton's law that says flow is proportional to pressure drop. Rather, their flow is proportional to the second or higher power of the pressure difference. This means that, if the pressure available at the nozzle varies 5% from shot to shot, the filling rates will vary by 10 to 20 percent. This in turn will cause variations in the amounts of material injected, the piece weights, and their dimensions. Similarly, if the runner design and layout is such that higher pressures are available at some gates than others, the cavities served by the low-pressure gates will deliver smaller pieces than those that are getting the higher pressures. They will also fill more slowly, may be weaker because of more severe frozen-in stresses, and sometimes do not even fill completely before the gate freezes off. For these reasons it is important, when close control of dimensions and properties is needed, to design gates and runners according to the principle of "successive simultaneity." This principle may be stated thus: the melt should reach all the gates at the same instant, the filling of all the cavities should be completed at the same instant, and the gates should seal at the same instant. The design of runner systems according to this principle was discussed in Reference 9 for the very common case where all the cavities are alike. Figure 2, p. 655, is a diagram of a layout for a 16-cavity mold that achieves successive simultaneity.

Considerable attention has been given in recent years to the speed of filling the mold (22, 11, 8). It is desirable, from the standpoint of avoiding thermal decomposition and shortening the time required for the piece to set up in the mold, to use a low melt temperature. However, as temperature drops, pieces freeze more quickly (as desired) and the cavities must be filled more quickly if they are to be filled at all. This requires faster rates of injection. Another important advantage of fast filling is this: the cavity is completely filled before viscosity has increased to the point where stresses connected with flow rise to a high level, and what stresses do arise have more time to "relax" before the melt freezes.

A characteristic of plastics is their viscoelasticity, or delayed elasticity. When they are subjected to stress—as they are during melt flow—a definite time elapses before the rate of flow reaches a maximum and becomes steady. Similarly, when flow ceases, a definite time is required before the stress decays to zero, i.e., relaxes. Unfortunately, these stresses increase with increasing viscosity at a given flow rate, and at temperatures just above the freezing point may be very large, approaching the strength of the plastic. Relaxation time also increases as the temperature drops. Thus, it is likely that if the mold is filled too slowly, parts of the melt will have frozen while in motion, and the severe stresses, unable to relax, will be frozen in. The effective strength in those parts of the piece will be reduced by the amount of frozen-in stress. Molded-in stresses in polystyrene have been investigated and reported on in References 37, 36, 34, 23, 22, 21, 15, and 11.

The realization that fast filling can reduce cycle time and improve quality—thus improving productivity in two ways—has resulted in "souping up" of injection machines until today the new machines have much higher pumping capacity at injection pressure than they used to have only five years ago.

Filling rate cannot be increased indefinitely without "burning" the melt. The great resistance that these materials offer to flow means that much work, per pound of material shot, must be done to get it from the nozzle into the cavity (26). This work appears as heat in the plastic. Where restricted gates are used, the usual case, much of the whole pressure drop occurs across the gate and its temperature may rise by 30° F. or more as it goes through the gate.

Aside from the effect of sudden viscous working, the melt may be burned even more severely if the rapidly filling cavity is not adequately vented. If the air that fills the cavity at the start of injection cannot escape rapidly enough it may be compressed to a tiny fraction of its original volume, and tremendous heat of compression is developed. The plastic in contact with this compressed air takes fire much as does diesel fuel injected into an engine cylinder under compression, and it is severely charred. Most molds can be satisfactorily vented by making some small scratches in the mold faces from the cavities to the outside of the mold. Venting may also be accomplished by leaving a small clearance around the ejection pin. With some shapes, however, unfortunate combinations of knockout-pin location and gate location result in air trapped in regions away from the parting line or the pins. Vacuum venting (7) is recommended for these cases and offers many advantages.

Ejection

With simple solid shapes, ejection is usually accomplished by having a metal finger, e.g., an ejection or knockout pin, poke out of the cavity surface as the mold opens, forcing the piece from the cavity. To be knocked out without being deeply marked, the freshly molded piece must have been chilled (e.g., "set" or "cured") to a temperature at which it has sufficient hardness. It must also have become stiff enough to hold its shape after it is deprived of the support of the mold.

Ejection of deep-draw shapes, (drinking tumblers, bushings, containers) is made much simpler and more reliable if the ingoing sides of the piece are slightly tapered, or given "draft." When no draft can be allowed—as is usual with bushings, gears, spools, and other machine parts—a knockout sleeve may be used in place of pins. The sleeve can apply a much larger knockout force than a pin without mutilating the piece because the force is distributed over the whole of the piece end and over a larger area. Ejection is also aided by materials known as mold releases. A typical release is any of several Freon-propelled silicone oils, and it is typically

sprayed on the mold surfaces when the mold is open, every few shots. Most silicone releases leave an oily film on the surfaces of the part and are objectionable if the part is to be printed, painted, or metalized after molding. Polymeric and wax-based releases are available.

In highly polished molds, the molded piece and the mold face may cling together as gage blocks do. An attempt to separate them by direct pull creates a partial vacuum and air pressure stubbornly holds them together. In such cases a fast jet of air directed at the edges of the piece facilitates ejection.

Mold design

Only a few vital points on mold design can be discussed here, since, in detail, this topic could fill a book the size of this one. The first is uniformity of temperature from cavity to cavity. The flow of melts is very strongly affected by changes in temperature, as has already been noted. If there are significant variations in temperature over the face of the mold (5° F. will often be too big a difference), the melt passing through the colder runners will flow more slowly, reach the gates late, fill more slowly and probably less, and freeze sooner. The results are cavity-to-cavity variations in dimensions and strength properties. From the standpoint of uniformity of product quality, *very uniform mold temperatures are a must* in multi-cavity molds. Temperature should of course not vary from shot to shot, even in single-cavity molds, for the same reasons. Getting this uniformity of temperature requires careful attention to the laying-out of the cooling channels in the mold and requires also an adequate supply of the cooling medium.

The second point, runner layout, has already been covered on p. 653.

A third important consideration is the projected area. The product of this area times the pressure in the mold, which may be as much as 80% of the ram pressure, must be well within the clamping capacity of the machine. In addition, the mold itself must be stiff enough so that it will not spring open under the hydrostatic separating force. If, for example, a long thin piece of sizable area is molded in the center of the mold, flash and erratic dimensions may be a problem unless the mold is given extra support at the center.

Fourth, for ejection's sake, some draft should be provided wherever possible in deep-cavity molds. Good mold design depends heavily on good piece design. Sharp corners, intricate outlines, draftless holes, etc., all tend to make molding more difficult and therefore more expensive.

Fifth, there should be a constant interchange of ideas among the product designer, mold maker, and molder for best results. Unnecessarily high tolerances increase mold costs; too loose tolerances on runners and gates can result in a high reject rate.

Sixth, the smallest possible gates consistent with good piece quality and complete filling of the cavities are usually specified, for this reason: when the frozen pieces are ejected, the runners must be separated from them; the smaller the gate, the easier is this separation. If the gate is small enough the runner can simply be broken off without marring the piece. Thus, small gates both facilitate operation, particularly automatic operation, and reduce finishing costs. Also, too-restricted gates are easily opened, whereas too-open gates are very difficult to close.

Last, when production runs are long, money spent on building tools helps later to reduce maintenance and down time. Some types of short-run tooling are discussed in the section on Plastics Tooling, p. 743. Metal-loaded epoxy tooling is discussed in Reference 14, p. 655.

Predrying of powder

Some plastics are hygroscopic, i.e., they extract water from the surrounding air and get wet. If they are molded in the wet condition, many troubles arise. The moisture cannot easily escape and may cause foaming at the nozzle during the mold-open time. Even slight foaming will cause smeared-out foam, or "splay," to appear on the surfaces of the pieces. Severe reductions of physical properties may occur as a result of water-caused degradation.

If the feed is predried, the drying is commonly accomplished by exposing the powder to circulating hot air (see Reference 2 for a discussion of the current status of this procedure). Since the powder is heated to about 180° F., if it is fed immediately, the injection machine is relieved of a substantial fraction of its heating load. Thus predrying, *alias* preheating, is an indirect way of increasing the plasticating capacity of an injection machine.

Annealing

As was noted above, molded parts sometimes suffer serious reductions in strength because of molded-in stresses. Conditions may be such that these stresses cannot be prevented during molding. If such parts are held at an elevated temperature for the proper time, these internal stresses will eventually relax (37, 36, 23, 15). The temperatures must not be too high, else they will warp or "stubbify" the resoftened part. The usual methods are to immerse the piece in a bath of hot liquid (water is common), or to keep it in a circulating-air oven for a while, the time depending on the material, temperature, the part shape, and the molding conditions. The annealing of some

materials is discussed in the individual articles on specific materials.

Preplastication

Preplastication is the technique, involving extra equipment, whereby the molding powder is melted in one chamber then transferred to the injection chamber before injection. Usually, the melting chamber is a cylinder much like the injection cylinder, though variations exist. Originally, preplasticators were developed to increase the shot capacity of the extra-large machines; the largest on record is rated for over 55 pounds. More recently, other advantages have become apparent (19, 8). Briefly they are: increased productivity because of faster cycles and reduced reject rates. Since there is no bed of recalcitrant particles in the injection cylinder, much lower ram pressures can be used, and much better control of injection pressure is attained. Because some mixing is accomplished as the melt is transferred from the melting chamber to the injection cylinder, melt temperature is more uniform. Very high injection rates are possible.

Mold temperature

In the paragraphs on Mold Design, above, the importance of mold temperature uniformity was discussed. Shot-to-shot uniformity, of course, requires not only shrewd coring, but also close control of the cooling medium temperature. This medium is nearly always water, but oil and steam have been used. On very small machines, molds may be electrically heated and air cooled.

It has been recognized that moldings harden faster in colder molds. Where flow properties permit, then, we should expect that the cycle could be shortened by lowering the mold temperature. Many molders are using refrigerating equipment of a compact, portable type to chill the water that circulates through the mold. Aside from keeping the mold colder, the technique provides close regulation of water temperature. It incidentally cuts the water consumption to almost nothing, an important consideration in dry areas. To avoid surface defects, the temperature of the mold faces must be above the dew-point of the air in contact with them. The effects of mold temperature on the flow of polyethylene and on the properties of molded polyethylene pieces have been investigated rather thoroughly (6). In brief: lowering the mold temperature increases strength and stiffness, improves clarity, slightly reduces surface gloss, and reduces cycle time substantially.

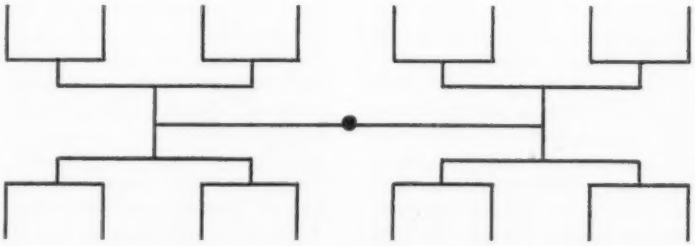

Fig. 2: Runner layout for a 16-cavity mold is designed so that melt reaches the gates at the same instant, filling of the cavities is completed at the same instant, and gates all seal at the same instant. All cavities are alike

The chapters directly following this one provide more detailed and specific information on the injection molding of the various thermoplastics.

References

Some of the following references were cited by number as giving more detail on certain points discussed in this chapter. Others, though not cited, are useful in learning what goes on in injection machines during the various phases of the molding process. All contain information applicable to the injection molding of most thermoplastics, though work reported in some of them has been restricted to a single material. The list is not exhaustive, and nothing on molding that appeared before 1949 is listed. Little of value, from the fundamental standpoint, appeared before that year. The breakthrough of the scientific approach to injection molding occurred in Reference 39, in 1950, and in other papers by the authors and their associates.

INJECTION MOLDING ACRYLICS

BY G. G. FREYGANG*

Acrylics are used primarily in those applications where their outstanding properties of optical clarity, outdoor stability, chemical resistance, and dimensional stability are of importance. It is, therefore, important that the handling and molding of these materials be consistent with these attributes.

Handling

The acrylics are not compatible with other plastics, and such mixtures will destroy the clarity of the molded parts. In similar manner, the three acrylic grades cannot be mixed without producing objectionable distortion.

Dirt, lint, and dust will detract from the clarity of the molded parts. Good handling practices are therefore of extreme importance. Because of the inherent tendency of practically all plastics to develop static charges, it is virtually impossible to prevent dust accumulation on reground material, even under ideal conditions. It is usually more desirable to use screened reground material in less critical parts than to blend it into virgin material with the possibility of degrading the entire mixture.

Molding characteristics

See Table I, p. 657.

Annealing: It has been established that the most stress-free molding (1)[1] will give the best service with respect to dimensional stability at elevated service temperatures, resistance to chemical attack, and long time outdoor exposure. Molding at moderate-to-high material temperatures, with adequate but not excessive pressure into warm and carefully controlled molds will produce the most stress-free parts (2). Annealing will tend to redistribute and lower the inherent molding stress and will produce superior parts. Annealing is imperative if the parts are to be decorated by painting or lacquering. In no case, however, should annealing be considered as a means to overcome poor molding practices.

Mold design: Well-designed

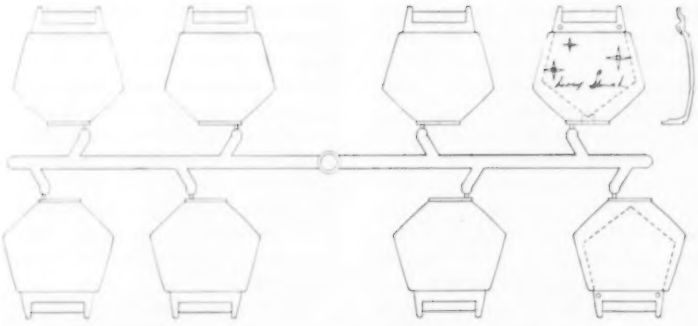
* Development Engineer, Plastics Laboratory, Rohm & Haas Co., Washington Sq., Philadelphia 5, Pa.

[1] Numbers in parentheses link to Special References on p. 658.

molds are an important adjunct to the production of well-molded parts. Adequate sprue, runners, and gates are necessary. For many parts, an 11/32-in sprue bushing, matched to a 9/32-in. nozzle, is satisfactory. Runners should preferably be full round, 5/16 in. in diameter if less than 10 in. in length, 3/8 in. in diameter if longer. Suggested gate sizes are listed in Table I, below. In multiple-cavity molds, balanced runner length, balanced gates, and balanced venting, if required, are all necessary if uniform fill patterns are to be maintained (3). Good mold design also provides adequate draft for easy release and sufficient knock-out points so that the parts are not stressed due to ejection. Properly designed molds seldom, if ever, require the direct application of mold release agents.

Predrying: Predrying of acrylics is recommended. Because of the inherent tendency to absorb some moisture, the acrylic molding powder may have varying amounts of moisture at the time of use, in spite of the care taken in its preparation and packaging. If the moisture content is high, molding conditions may have to be modified to suppress defects due to this moisture. The usual remedies are lower material temperature and higher pressure, both of which will cause more highly stressed, and thus less serviceable parts. Predrying also contributes toward a more uniform feed temperature, particularly if hopper dryers are used. The uniform feed temperature in turn contributes to more uniformity in material temperature and pressure.

Hopper driers and ovens can be used. In the hopper drier, 3 hr. at 180 to 200° F. is recommended; in ovens, 2 hr. at 180 to 200° F. is recommended.



Machine capacity: The selec-

tion of machine size will have an influence on the quality and yield of molded parts. Normally, the best results are attained if the shot weight is no more than 75% of the machine capacity. Molding over this capacity may produce material temperature variations within the shot and lower the available pressure at the mold. Excessive over-capacity of the machine is also undesirable.

Recommended temperatures for rear cylinder, mid-cylinder, forward cylinder, nozzle, and mold face are listed in Table I, p. 657. The temperature of the melt as it leaves the nozzles is also listed in Table I.

INJECTION MOLDING CELLULOSICS

BY P. H. ERICKSEN*

The four types of cellulose plastics having volume usage for injection molding applications are cellulose acetate, cellulose propionate, cellulose acetate butyrate, and ethyl cellulose. Each has its distinguishing characteristics, but being of the same family they are similar in a number of ways. In particular, these plastics are noted for their toughness, dimensional stability, surface appeal, almost unlimited color range, heat stability, and ease of molding and fabrication. They are all prepared from their basic polymers into workable plastic form by compounding with proper plasticizers.

A number of different plasticizer types are used, and it is quite common to combine two or three to advantage. By virtue of the modifications which can be made in formulation, very broad ranges of physical properties and molding characteristics are possible. Through proper selection of base polymer and type and amount of plasticizer, specific property combinations can be "designed" into the plastic.

*Cellulose Products Dept., Hercules Powder Co., Inc., Parlin, N. J.

Handling

Predrying: To obtain good results in molding cellulosics, proper drying is essential, particularly since these plastics are slightly hygroscopic in nature. Presence of excessive moisture is cause for such defects in the molded piece as surface mica, blisters, and bubbles. Drying of the granules to a moisture content of 0.2% or less is recommended. This may be accomplished in the following manner:

Type of equipment: Hopper drier or circulating-air oven (tray drier)
Drying time, hr.: 2 to 6
Dry temp., °F.: 160 to 200

In hopper driers, the higher temperature levels up to 200° F. can be used if it is known that the material in use will not tend to lose its plasticizer through volatilization or become tacky and bridge across the hopper throat.

If a tray drier is used, the recommended depth of granules in the trays is about ¾ inch.

Infra-red driers can also be used. Among infra-red driers, those best suited to production use are endless-belt or vibrating-conveyor units, which in a continuous type of operation pass the granules in a thin layer under infra-red lamps for a controlled exposure.

Handling: Care in handling to avoid contamination is necessary, but no special handling conditions are required.

Equipment and molds

Equipment: No special equipment is necessary when molding the cellulosics. Certain recommendations are offered, however.

For example, a heater band for the *nozzle*, with separate Variac control, is recommended. Generally, 100 w. is adequate. The heat should be adjusted to give a slight pull-out of plastic melt on the nozzle end of the sprue.

Large-hole nozzles are also preferred for easier fill because they lessen pressure loss. The size, however, will necessarily be slightly under that of the sprue's minimum diameter.

Recommended materials of construction for *cylinders* and *spreaders* are SAE 4140 or 4340 steels.

Mold design: Identical-cavity layouts are highly preferable to "family" molds from the standpoint of balanced flow, simultaneous filling, and minimizing of flash. A flash chrome plating of cavities is recommended.

Gating: See Table I, p. 660, Section D. Dimensions listed in Table I are based on the restricted type of gate and are applicable as starting recommendations for all cavity sizes within the given limitations. Gates may

be enlarged, particularly in the large-size heavier-thickness cavities, if necessary.

Except possibly for relatively large moldings, the restricted gate has a number of advantages over the full-open type. Properly applied, it provides improved uniformity of flow-out, minimizes turbulences and resultant stresses, and enables better escape of gases from the cavity. Also, more rapid setup at the gate acts to eliminate sinks and flow-back and in turn enables a shorter piston-forward time in cycle. Another advantage is reduced trimming and finishing.

At the same time, the tendency for somewhat lower impact strength to occur near the gate area should be kept in mind. Generally, with restricted gating, it is desirable to gate into the thin cross-section end of a cavity. The plastic should enter the cavity in a direction perpendicular to the main direction of flow within the cavity and directed against an opposing wall or pin so that the center of flow is dispersed. This provides more uniform fillout and eliminates "worming."

The molding of mottles through restricted gating will result in a blending-out effect, but as the diameter approaches 0.050 in., good pattern can be obtained.

Runners: A recommended layout of cavities and runner system would feature the following: 1) equal runner distance from sprue to all cavities; 2) a balance in cavity distribution by having an equal number per runner and per branch of runners; 3) full-round runners; 4) a stepwise reduction of 1/32 in. in runner diameter from sprue to cavities at each branching of the system; and 5) an over-run of the runners past the gates, or past the secondary sprues if center-gated, and also at appropriate junctions in the system to function as cold-slug wells.

As a rule, runner diameter can be gaged by the thickness and size of the piece to be molded. Common sizes are 1/4 and 5/16 in. with a minimum of 3/16 in. recommended. Oftentimes, undersized runners rather than gate size are cause for such difficulties as mica, lamination, and lack of ease in mold fill. Thus, it is advisable when using restricted gating to be assured that runners are adequate before opening the gates. A runner connecting to a gate should not be tapered in its approach but should be kept full and should end in a hemispherical contour. This helps to minimize pressure loss.

Molding characteristics

See Table I, p. 660. To cover this extremely broad class of molding compounds over the flow grades commercially available, fairly wide ranges are used in the tabulation of figures in Table I. For example, some of the softer compositions can be molded as low as 350° F., whereas the harder, less-plasticized formulations may require as high as 500° F. Allowance for differences in injection molding machines, type of part being molded, mold design, etc., was also taken into account.

The approximate operating conditions are therefore offered only as a guide for start-up.

Cylinder temperature: A good rule-of-thumb, regardless of type or formulation, is to work at the highest cylinder temperatures feasible for good operation. This is important, particularly for the harder, higher-flow materials, in order to develop maximum impact resistance and elongation, to minimize molded-in stresses, and to avoid weak welds. This temperature is generally slightly below the point at which traces of discoloration occur. Some exceptions to this are found where other limitations are encountered prior to reaching this temperature level; i.e., defects such as flash, sinks, voids, heat marks, and vapor burns. These exceptions will occur for the most part with the lower-flow materials, where the need for approaching the discoloration point assumes less significance.

In molding ethyl cellulose, particularly where relatively thin sections are required, use of maximum allowable temperatures should receive special emphasis. If molded on the "cold" side, the piece may look good but is likely to be laminar, or have a peelable surface skin, and will tend to dull or "rub-up." Higher-flow grades are more apt to show these defects than the softer compounds.

Flow temperature as measured by the standard ASTM test, D569-48, is commonly used with the cellulosics as a means for control and identification. This is the temperature at which a plastic under 1500 p.s.i. pressure will flow through a standard 1/8-in. orifice for a distance of 1 in. in 2 minutes. It is recognized that the rates of shear and the conditions of temperature and pressure, in addition to other basic differences, are quite unlike those occurring in an injection molding process. For these reasons, the test is not a precise indication of relative molding characteristics, unless the plastics compared are from a given polymer-plasticizer system. Therefore, for example, it is not at all uncommon to have two cellulose acetate plastics of the same flow which differ significantly in molding characteristics.

In view of this, an unqualified use of flow to indicate molding temperatures should be considered as only a rough guide for start-up. The following approximations for average conditions are provided on this basis:

Flow[1]	*Cylinder temp.* (°F.)
H4 — H5	455 — 510
H2 — H3	435 — 495
MH — H	405 — 465
MS — M	370 — 430
S2 — S	340 — 400

If the melt in the cylinder is kept hot too long, it degrades. Top safe temperature for 20-min. exposure is 350 to 400° F.

Nozzle temperature: If the nozzle or cylinder heats are excessive, the plastic will drool. This is not only a waste of plastic but is objectionable in that some of the oozed material enters the sprue bushing prior to the injection stroke, becomes chilled, and may cause plugging at the cavity gate or surface defects in the part.

Mold temperature: Precision work requires close control. Proper coring of the die and a temperature-control unit capable of maintaining the circulating

[1] See ASTM test D569-48, 1955 Book of ASTM Standards, Part 6, p. 287, for definition of these flow designations.

TABLE I: Injection molding characteristics of cellulosics

(Recommended molding conditions for various section thicknesses)

Thickness of section:	*less than ⅛ in.*	*⅛ to ¼ in.*	*over ¼ in.*
A. Temperatures, °F.			
1) rear cylinder	340-510	340-490	340-480

E. Shrinkage allowance, mils/in.	Without annealing	Without annealing	Without annealing
1) in direction of flow	2-7	2-15	4-25
2) perpendicular to flow	2-7	2-15	4-25

[1] Gating dimensions listed are based on the restricted type of gate and are applicable as starting recommendations for all cavity sizes within the given limitations. Gates may be enlarged, particularly in the large-size, heavier-thickness cavities, if necessary. See also text, p. 658.

water at ±2° F. are essentials. Optimum temperature level will depend primarily on size and thickness of the part and on the plastic formulation. For relatively high-flow compositions, especially where long, very thin sections are being molded, temperatures as high as 180° F. may be needed. For the softer formulas, a low in the vicinity of 70° F. is not uncommon. However, most jobs will fall within a 120 to 160° F. range. For obtaining maximum surface gloss, plus minimum weld lines and flow marks, the highest temperature which will provide adequate set within the cycle limitations should be used.

Pressure: In general, the optimum is a combination of maximum pressure and minimum booster which will provide unhesitating fill without encountering flash or sinks.

Cycle: The cycle is primarily governed by section thickness, plastic formulation, cylinder temperature, die temperature, and the ease of ejecting the molded part from the cavity. The injection portion of the cycle should be of adequate length for setup to occur at the gates of the cavities. Otherwise, flow-back with resultant sinks or voids in the part will occur. The cooling portion of the cycle should then be the minimum needed for prevention of distortion on ejection and during further cooling.

Purging routine: Purging is done with commercial purging compound, scrap, or the material to be molded. Purging is generally necessary at start-up, or after excessive heat exposure due to hold-up or when changing over from another material.

Design of molded part

Prior to new die construction, first consideration should be given to the design of the article.

Dependent on design and important for successful molding are: 1) flow of the plastic in filling the cavity; and 2) ease of ejection of the molded part.

The general shape and dimensions of the proposed molding and the gate location are principal factors affecting flow through the cavity. Their combined influence should be directed toward achieving an unhesitating, balanced progression of the plastic during cavity fill. If flow from the gate to the extremities is not uniform, or if the flow becomes divided, trapping of gases and weld lines are likely. Wall thickness is a very important controlling feature, and even small variations toward an unbalanced condition can cause trouble. Sudden changes in the thickness should also be avoided because of a shrinkage differential on cooling which is likely to cause distortion or highly stressed areas. On center-gated items, it is good practice to provide a gradual decrease in the wall dimension as the distance from the gate increases. This tends to prevent unbalanced fill; furthermore, with deep-drawn parts, the draft obtained is necessary for ejection.

Where holes and inserts are re-

quired, it is well to avoid, if possible, square or rectangular shapings, since flow at these points tends to cause a weld line and also pigment orientation.

No matter what the final design is to be, however, the recommended molding conditions listed in Table I, p. 660, can be taken into account. These recommendations have been broken down to provide for variations caused by differences in wall section thickness. The three categories covered are: section thicknesses less than ⅛ in.; section thicknesses between ⅛ and ¼ in.; and thicknesses over ¼ inch.

INJECTION MOLDING POLYTRIFLUOROCHLOROETHYLENE*

Polytrifluorochloroethylene (TFCE) may be injection molded successfully in conventional equipment, although temperatures required for processing are higher than those for most other polymers. Injection pressures are also generally higher—40,000 to 60,000 p.s.i. are not uncommon—although pressures as low as 20,000 p.s.i. can be used. Because of the ever-present danger of molecular-weight degradation, it is recommended that pressure rather than cylinder temperature be increased when better mold fill-out is desired. The geometry of the casting and mold design, as well as the ratio of cylinder capacity-to-weight of shot, are also of prime importance. Table I, right, is suggested as a starting point for most molding jobs, although proper molding conditions should be determined by experimentation in each case.

TABLE I: Suggested injection molding conditions[1]

Fluorothene grade:	*FYTD*	*FYTH*	*FYTS*
Cylinder temperature, °F.	520-560	540-580	560-600
Mold temperature, °F.	280-300	280-300	280-300
Ram pressure, p.s.i.	20,000-30,000	20,000-30,000	20,000-30,000
Injection dwell, sec.	10-50	10-50	10-50
Clamping dwell, sec.	10-30	10-30	10-30
Total cycle, sec.	30-90	30-90	30-90

[1] Based on Bakelite Co. materials.

Due to the extremely high viscosity of TFCE, small passages such as pinpoint gating should be avoided. Streamlined flow and minimum restriction in sprues and runners are necessary to avoid the use of excessively high cylinder temperatures and/or injection pressures.

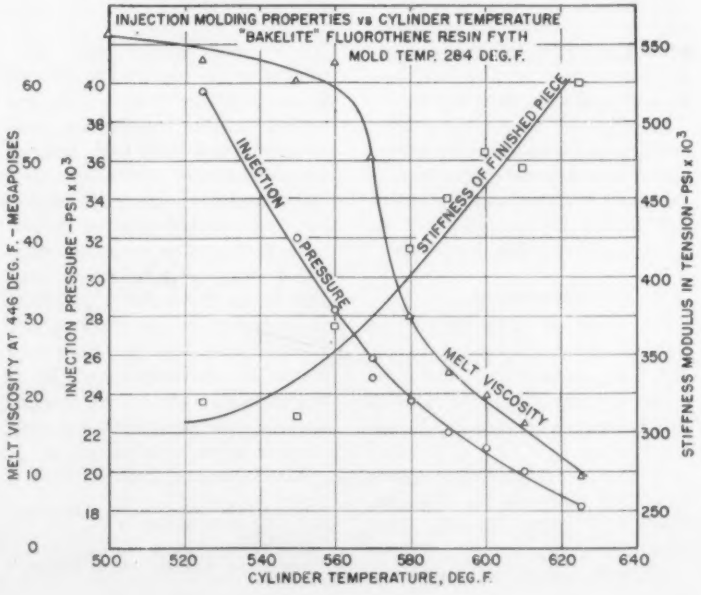

Figure 1, right, illustrates the effect of cylinder temperatures on injection pressure, melt viscosity, and stiffness modulus of the molded item. The effects of mold temperature on injection pressure and mold shrinkage are illustrated in Fig. 2, p. 662. The more rapid cooling rate which accompanies the use of lower mold temperatures aids in producing parts of greater transparency. Figure 3, p. 662, illustrates the effects of cylinder temperatures and mold temperatures on injection pressure. As can be seen from these figures, melt viscosity of the compound being molded is of prime importance. The data presented in these figures represent conditions for molding an A.S.T.M. Type 1 end-gated tensile bar on a 3-oz. press. The results, of course, would vary with changes in the type of mold or injection machine.

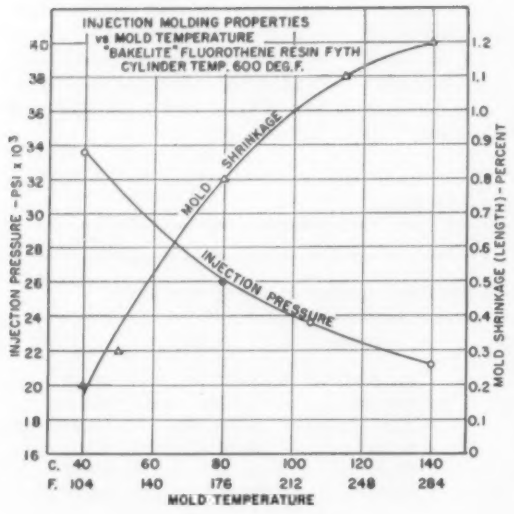
When heated above its melting point, TFCE is quite corrosive to many metals and organic contaminants. It is recommended that all metal surfaces that contact the hot polymer be chrome-plated, unless, of course, the metals are highly corrosion-resistant, e.g., No. 304 stainless steel and such alloys as X nickel, Xalloy 306, and Hastelloy Alloy B. Contaminants such as polyethylene, vinyls, or other organic matter may seriously degrade TFCE at processing temperatures.



Molding characteristics

Some general recommendations can be made with regard to the molding of polytrifluorochloroethylene. For one thing, most

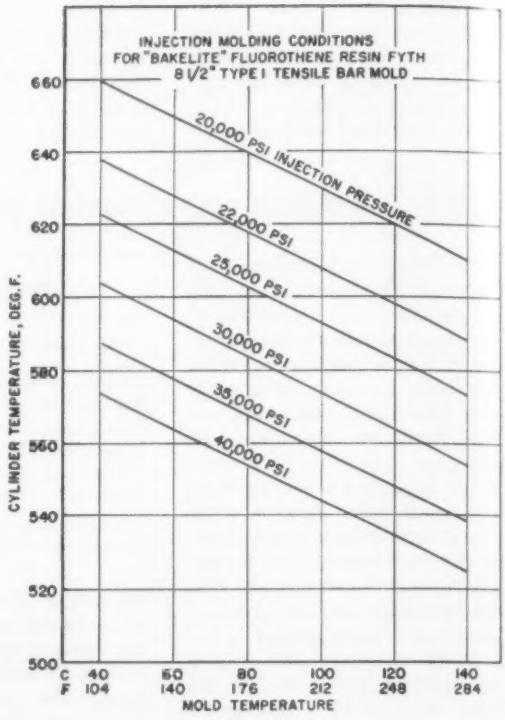

Fig. 2 (above): Effect of mold temperature on injection pressure and mold shrinkage. Fig. 3 (right): Effect of cylinder temperature and mold temperature on injection pressure. The data presented in these figures represent conditions for molding an ASTM Type 1 end-gated tensile bar on a 3-oz. injection molding machine

gates used when molding the material are ⅛ in. or greater and are center-gated. Another factor to bear in mind is that if the melt in the cylinder is kept hot too long, it degrades and the molded pieces suffer from discoloration, brittleness, poor surface, etc. Top safe temperature for 20-min. exposure is 400° F.

Predrying of molding powder can be done in a circulating-air oven. Recommended drying times are from 1 to 2 hr. at a temperature of approximately 200° F.

Purging may be necessary when molding polytrifluorochloroethylene if the material degrades and discolors. In this event, the cylinder should be purged until no more discolored TFCE appears.

INJECTION MOLDING NYLON

BY LOUIS PAGGI*

Since good quality and close tolerances are specified in most of the applications of nylon, the injection molding operations must be performed with care and all variables closely controlled.

Successful molding of nylon requires consideration of certain basic factors. For example, nylon has a sharp melting point (e.g., 487° F. for Zytel 101[1]). At molding temperature, the material has a lower melt viscosity than conventional thermoplastics. It is therefore necessary to modify conventional equipment and procedures when molding nylon.

Plasticating cylinder: With a correctly designed nozzle and proper distribution of heat, injection cylinders of all designs can be used for molding nylon. In general, it is found that horizontal diverging-type cylinders (Figs. 1 and 2, p. 663) and vertical cylinders can be heated to a higher over-all temperature than is possible with horizontal straight-bore cylinders.

Failure to carry sufficiently high temperatures at the rear section of diverging and multi-channelled cylinders may result in bridging of the granules, causing drooling at the nozzle, loss of injection pressure, local degradation of the material, and reduced output.

The type shown in Fig. 1 (typified by the De Mattia, HPM, Impco, Fellow-Leominster, Reed-

Prentice, and Watson-Stillman machines) has no heating band over the course traveled by the plunger. The rear heating zone is at the rear section of the spreader. For this type of cylinder, the highest temperature (600° F. or hotter, depending on thickness of section, cycle, etc.) should be maintained at the rear band (measured at the center of the heater band). A temperature about 50 to 150° F. lower is maintained over the front portion of the spreader section. The temperature at the extreme front end of the cylinder should be just high enough to keep the material moving through the nozzle—as low as 400° F. on fast cycles, or as high as 500° F. on slow shots.

In the cylinder design shown in Fig. 2 (exemplified by the Lester and Van Dorn machines), the rear heating zone overlaps a section of the plunger stroke. The rear band of such a cylinder should be heated only to about 450° F. The higher temperature is applied at the main body band. For the front portion of the spreader and the extreme front end of the cylinder, the same general rules apply as for the cylinder in Fig. 1.

Nozzle: Recommended for molding nylon is a nozzle with a reverse taper bore at least 1 in. in length. This, in effect, extends the sprue into the heated nozzle. This design permits operation of the nozzle at a lower over-all temperature, eliminates the likelihood of a hot spot at the rear of the nozzle, and provides good control over drooling. For the best results, this type of nozzle should be provided with a heater band of sufficient wattage to maintain a temperature of at least 600° F. This band should be located as close as possible to the outlet of the nozzle and the sprue bushing, and should not exceed 2 in. in length.

It is important that the nozzle be adjusted to the sprue bushing only after the plasticating cylinder is up to molding temperature. If the nozzle is tightened against the sprue with a cold cylinder, the thermal expansion of the cylinder will wedge the nozzle too tightly against the hard sprue bushing, causing peening-in of the front opening. A damaged nozzle will not operate as designed and is hard to control.

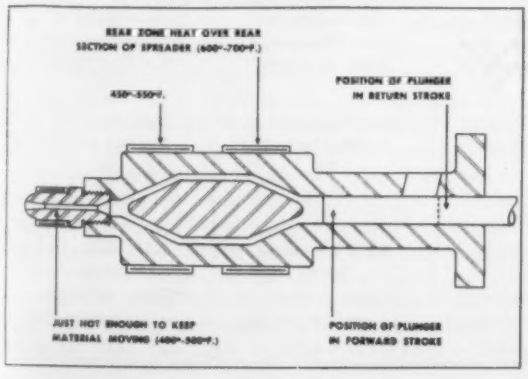
At least one commercial machine is equipped with a nozzle having a mechanical shut-off. This type of nozzle has proved successful in molding nylon; in fact, it offers certain advantages when molding over inserts, or when very hot material is required at the front end of the cylinder, as when molding extremely thin-walled sections.

Mold design: Special mold construction is not required for nylon. Although molten nylon is more fluid than other thermoplastics, it will solidify almost at the instant of contact with the relatively cold mold surface, thus eliminating any undue tendency to flash. When flashing occurs, the line pressure should be reduced but the high rate of injection maintained. It should be noted that a common cause of flashing as well as surface burns is due to insufficient venting of the cavities. Because of the high rate of injection necessary for nylon, good venting of cavities is important at the spot where air traps. The preferred method of venting is an overflow button or slug positioned diametrically opposite the filling gate and connected to the cavity with a gate and runner of approximately ½ the cross-section of the filling gate.

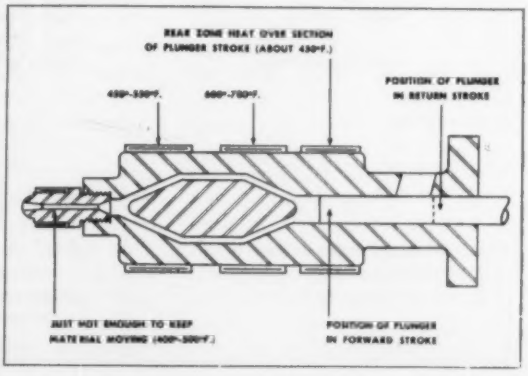
Rough ground parting lines would be a second choice.

Lapping of the mating surfaces of the cavities is not recommended when injection molding.

Molds for articles which do not demand close tolerances can be designed by using data accumulated through experience or by allowing for a shrinkage of 0.010 to 0.040 in./in., depending on the wall section of the article. When close tolerances are required, however, the following mold construction steps are recommended:



1) Using the specified dimensions, machine a single cavity in the mold-base intended for use in production.



2) Machine the sprue bushing and all runners up to the positions where the production cavities will be inserted. This will establish the time required for the material to reach the cavities.

3) By trial moldings in the single cavity, determine optimum runner and gate size, and determine the best molding conditions required.

4) Heat-treat the molded part

Figs. 1 and 2: With proper distribution of heat, cylinders of all types can be used for molding nylon. Of the two major types of heater distribution, the cylinder in Fig. 1 (left) requires higher rear zone temperatures because the heater band does not extend over the plunger path

for ½ hr. at 350° F., and allow to cool slowly. (See paragraphs on "Heat-treating," p. 665.)

5) Check dimensions of the treated article after at least 24 hours. Note changes in any dimension.

6) Use shrinkage data thus obtained to adjust the dimensions of the production mold which is to be constructed.

Gating: See Sec. D, Table I, below. In general, runners should be between ⅛ and ⅜ in. in diameter. For articles having a wall thickness of ⅛ in. or less, runners need not exceed ⅛ in. in diameter. For articles of heavier wall thickness, the diameter of the runners should usually be about ½ to ⅔ the thickness of the article, though not exceeding ⅜ in. in diameter.

Dimensions for gates are given in Table I, below. If possible, gates should be flared toward cavities.

Predrying

Material molded with a moisture content above 0.25% will give moldings or extrusions with reduced toughness. The molding powder should therefore be stored in covered, moistureproof containers. Hoppers of machines should also be covered to minimize contamination by moisture.

It is recommended that nylon be molded fresh from the can. After opening the shipping container, nylon molding powder can stand (on humid days) for only 20 min. before predrying is necessary. Drying can be done in a dehumidified air oven at 175° F. Drying time would be between 3 to 6 hr. for virgin material and 12 to 24 hr. for reground material.

Molding characteristics

See Table I, below.

Molding temperatures: In many cases, the use of higher molding temperatures (600 to 700° F.) improves the properties of the molded piece (especially toughness), permits the use of smaller runners (hence gives less scrap

TABLE I: Injection molding characteristics of nylon

and shorter cycles), and increases the plasticating capacity of the machine from two to four times that possible with temperatures of 550 to 600° F.

Moldings of thin section, produced in short cycles and at high rates of material consumption, require higher cylinder temperatures than moldings of heavier section, longer cycles, and low rates of material consumption. For example, in the case of a 6-oz. shot being molded on an 8-oz. machine at a rate of about 11 lb. of nylon per hr., a temperature of 520 to 600° F. is indicated. If the same 8-oz. machine is used to mold a 2-oz. shot every 20 sec. (or about 22 lb./hr.), a higher temperature will be required. An output of greater than 40 lb./hr. on the same machine may necessitate cylinder temperatures as high as 720° F.

Mold temperatures: In general, the temperature of the mold should be about 100° F. Lower temperatures may be used when extreme toughness in thin sections is desired. Temperatures as high as 250° F. may be used when a more stress-relieved article is desired but where extreme toughness is not absolutely necessary.

Molding cycles: Articles with nonuniform cross-section, in which edges or surfaces must be extremely straight or flat, will usually require longer cycles.

Purging routine: After 15 min. delay, purge repeatedly until ram labors.

Heat-treating

To insure against any dimensional change caused by stress-relief, it is important that residual stresses be relieved by heat-treating the articles soon after molding.

It is recommended that heat-treating of nylon be carried out in the absence of air, preferably by immersion in a suitable liquid. The temperature of the heat-treating liquid should be well above the temperature to which the article of nylon will be exposed in use, preferably about 350° F. This will insure against dimensional change caused by uncontrolled stress-relief occurring below this temperature. Upon removal from the heat-treating bath, the molded article should be allowed to cool slowly in the absence of drafts; otherwise new surface stresses may result. A simple way of insuring slow, even cooling is to place the heated article in a cardboard container.

High-boiling hydrocarbons, such as oils or waxes, may be used as heat-transfer medium if the deposit left on the surface of the article is not objectionable. The minimum immersion time required for heat-treating is 10 min. for articles having a wall thickness less than ⅛ inch. Articles of heavier cross-sections may need up to 30 minutes.

Defects and causes

Blisters and splay marks: a) Wet or overheated materials; b) slow filling of mold; c) front of cylinder too hot, rear too cold.

Weld marks: a) Material too cold; b) pressure too low; c) slow filling of mold; d) poor venting.

Burn marks on surface: a) Poor venting; b) filling too fast.

Discoloration or brown streaks: a) Rear heat of cylinder too high; b) too much wattage over section of cylinder where injection ram works; c) insufficient pad of material between ram and cylinder after shot is taken; d) ram outtime too long; e) long delays between cycles; e) machine operating a short time after start-up.

Reduced toughness: a) Wet or overheated material; b) mold too hot; c) nonuniform wall sections in part; d) sharp angles in flow within the cavity (Where possible, use radius at meeting of any two sections.); e) wrong position of gate (Do not locate gate at any point where flexing occurs.); f) gate too sharp at entry to cavity (Blend with generous radius.); g) excessive dirt, fillers, or pigments used in material.

Inability to hold dimensional tolerances: a) Erratic performance of hydraulic or electric systems of machine; b) nonuniform cycles; c) gates too small and/or too long; d) runner system too long or too complex; e) too many cavities; f) worn clamp platen bearings; g) mold leader pins binding; h) nonuniform feeding of material; i) material not uniformly dried.

Ejection difficulties: a) Insufficient draft angle; b) cavity surfaces too smooth; c) cycle too short or too long; d) material injected too hot; e) wrong type of knock-out; f) wall sections too thin; g) pressure too high or low.

Internal voids and surface sinks: a) Pressure too low; b) cycle too short; c) filling rate too fast; d) material too hot; e) gates too long and/or too small; f) runners too small; g) lack of radii in flow stream.

Hazards

Nylon is not a dangerous material to handle, provided it is recognized that it is very hot and very fluid in its molten state. Moisture in the nylon does not make it more dangerous.

In general, molding powders heated to elevated temperatures in a confined space expand considerably and generate pressure which, when released, can cause molten material to be expelled from the cylinder with considerable force. Long delays in the molding cycle increase the possibility of violent ejection, particularly if the material in the rear section of the plasticating cylinder and the material in the nozzle are allowed to solidify due to a temperature drop, while the center and front sections are maintained at well above the melting point. This results in the formation of a solid plug of plastic at either end of the molten material under pressure. To prevent this from happening, the nozzle should be free from contact with the sprue bushing during the heating period prior to molding. The nozzle and front end of the cylinder should be heated first and maintained at a temperature at least 50° F. above the rest of the cylinder. As soon as the plastic flows from the nozzle, the remainder of the cylinder may be set to the proper molding temperature. When the rear temperature is sufficiently high to permit moving the ram, at least one air shot should be taken before locking the nozzle against the sprue bushing. The rear temperature of the cylinder should then be maintained high enough to allow free movement of material entering the rear zone.

If the melt in the cylinder is

kept hot too long, it degrades and the molded pieces are liable to suffer from such defects as discoloration, brittleness, poor surface, etc. The top safe temperature for 20-min. exposure is 550° F.

INJECTION MOLDING BRANCHED POLYETHYLENES

BY G. W. JARGSTORFF*

With the increased use of branched (low-density) polyethylenes in a larger variety of molded objects, extensive investigations have been initiated to study the important factors involved in their injection molding. The results of these studies have been primarily a rather clear definition of the importance of each factor in the injection molding process. Briefly, the results confirm field experience that the injection temperature or stock temperature is of primary importance. Two other major variables —injection pressure and mold temperature—were found to have an effect which is of lesser degree.

Figures 1 and 2, below, and also figures 3, 4, and 5, p. 667, show a marked effect on select properties with the variation of material temperature during injection. In the tests on which these graphs are based, temperatures ranged from 350 to 550° F. (as measured from molten stock on cycle). Mold temperatures were varied at each injection temperature used, from 70 to 130° F.; injection pressures were varied at each of the combinations of both of the temperatures.

Since the data shown were assembled from results obtained from a single machine and mold, absolute values may not be applicable to specific conditions in the field. However, the trends shown are entirely valid and have been corroborated for a number of different grades of polyethylene. They may therefore be applied as a guide to the injection molding of polyethylene regardless of the machine or the mold that is used.

Injection temperatures given in the figures are the actual temperatures of the molten material, taken by needle pyrometer measurements on cycle. Experience has demonstrated that the actual stock temperature, in the majority of cases, runs well below that of the cylinder as read from indicating instruments. The importance of determining actual stock temperature in the injection molding of polyethylene, or any other thermoplastic, will become apparent later in the discussion.

How properties change

Referring to the figures for each property, it is found that, as the injection temperature increases, tensile strength in the direction of flow decreases asymptotically to a minimum (i.e., approaches a minimum value as a limit); brittle temperature improves; stress-cracking resistance is increased; gloss and skinning resistance to surface delamination are improved; and shrinkage decreases asymptotically.

It may seem odd that raising the stock temperature should *decrease* the shrinkage since plastics expand with rising temperatures. It would be expected that, other factors remaining the same, if the melt were injected at higher temperature, having further to cool, it would shrink more, not less. The clue lies in the phrase "other factors remaining the same." As the stock temperature is raised by raising the cylinder temperatures, a much larger fraction of the cylinder contents is melted. The pressure drop between ram and nozzle, consumed in forcing the cold granules into the constricted heating zone, is greatly reduced. Thus the stock pressure in the mold increases even though the ram pressure has not been changed. This increase results in higher melt density with a corresponding expansion of the piece due to decompression when it is ejected from the mold. Since the percentage increase in stock pressure is much greater (quite possibly 100% or more) than the increase in *absolute* temperature of the stock (roughly 10% for a rise of 80° F.), the pressure effect more than offsets the temperature effect, with the observed results.

This interaction of molding factors is unavoidable and points up the need for measuring not only stock temperature but also *stock pressure* and stock injection rate. Ram pressure is as little useful as cylinder temperature in establishing the state of the stock.

From the above analysis, it is plain that increasing the length of a short cycle will have some of

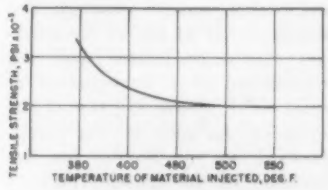
Fig. 1: Variation of tensile strength with injection temperature changes



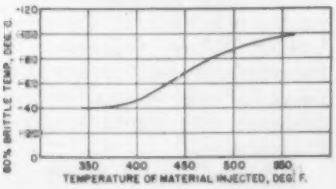


Fig. 2: Variation of 50% brittle temperature with injection temperature changes

the effects of raising the cylinder temperature. The effects of using a preplasticator may also be predicted from the same considerations.

Strength vs. temperature

It may be stated generally that better polyethylene moldings are obtained when higher material temperatures are employed. Although tensile strength in the direction of flow is greater at lower injection temperatures, this is an anisotropic effect due to orientation (i.e., values vary depending on the direction of measurement); strength transverse to the direction of flow usually suffers. As the injection temperature increases, the tensile strength of the piece may be observed to approach that of compression molded polyethylene; anisotropy diminishes and shrinkage values are found to be lower in the direction of flow. The degree of anisotropy induced during molding will also vary from application to application, depending on the particular mold design, other conditions being constant.

It may thus be stated that the properties of injection molded polyethylene are strongly dependent on the fluidity achieved in the heating cylinder and on the fluidity and resistance of the runners, gates, and cavity sections to flow during the short but critical period required to fill.

Pressure vs. properties

Pressure also affects the properties of the molded piece, but to a lesser degree. Most properties, such as stress-cracking, skinning, and brittle temperature, are affected only slightly by pressure at any injection temperature. Shrinkage is decreased and tensile strength is materially decreased in the direction of flow by increased injection pressure. The effect of pressure is more pronounced at lower injection temperatures. By increasing pressure and filling the mold faster, a greater average fluidity is maintained in the mold during filling.

The effect of mold temperature on properties is not significant with the exception of gloss, which is generally improved by higher mold temperatures. The effect of mold temperature on cycle is small at injection temperatures below 450° F., but at higher temperatures it becomes rather critical, having a large direct effect on cycle. In addition, since changes in cycle length affect stock temperature and pressure, there are effects which are indirect, as well.

Table I, p. 668, summarizes suggestions for improving the injection molding performance of most commercial grades of polyethylene resins. Inevitably some compromises will have to be made where two properties require different techniques. In these cases the individual application will determine the proper procedure to be followed.

Molding techniques

Obviously, the length of cycle is an extremely important economic factor in injection molding. The emphasis in every injection molding job is on minimizing the cycle. As a result, machines in the field today are running materials on ever-shorter cycles. Molders are also interested in getting as large a shot as possible out of a given machine. This has been responsible for the development of preplasticators and higher-wattage heating cylinders.

These two factors are loading present machines to their limit and in many cases overloading them, with the result that material temperatures are falling far below those indicated for the injection cylinder itself. It is apparent that as cylinder throughputs increase and cycles decrease further, material temperatures will continue to drop even though indicated cylinder temperatures remain the same.

Product quality

The quality of the injection molded product is highly dependent on the melt temperature during injection. Therefore it is not enough merely to soften material to the point where it will fill a mold; rather, the material must be delivered at the proper temperature and plasticity for a given mold to obtain optimum properties. Thus, when reference is made to the plasticating capacity of an injection machine, it is not

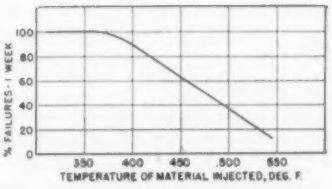

Fig. 3: Variation of stress-cracking resistance with injection temperature changes

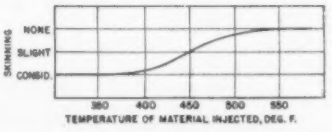

Fig. 4: Variation of skinning resistance with injection temperature changes

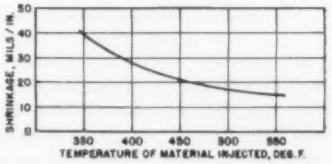

Fig. 5: Variation of shrinkage with injection temperature

enough to specify merely the rate of throughput; the temperature of the material in question being delivered at that rate of throughput is another important specification which must be made.

In cases where there is some latitude in temperatures available on a given machine for the fastest throughput possible, the next question is that of the temperature to select for a given molding application. This, of course, will depend on the particular configuration of the cavity to be filled. For pieces containing thin sections, higher temperatures will be required than for pieces having heavy-walled sections. The piece molded in the study mentioned above consisted of a thin plaque with a maximum thickness of 0.075 in. and a minimum thickness of 0.033 inch. In this case, in order to minimize skinning, stress-cracking, shrinkage, and orientation, and to get optimum low (brittle) temperature properties in the finished polyethylene piece, it was necessary to mold at material temperatures of 550° F. or higher. Since these thicknesses are in the range of wall thick-

TABLE I: Suggestions for injection molding polyethylene

Property desired	*Technique used*
Fast molding cycle	Min. stock temperature; min. mold temperature
High gloss	Max. stock temperature; max. mold temperature; restricted gating.
Improved fill out	Max. stock temperature; max. injection pressure
Low shrinkage	Max. stock temperature; max. injection pressure; min. mold temperature
Low warpage	Max. stock temperature; min. injection pressure; balanced mold temperature
Low brittle point	Max. stock temperature; max. mold temperature
Good skinning resistance	Max. stock temperature; min. mold temperature
High strength or stiffness in direction of flow	Min. stock temperature; min. mold temperature
Good stress-cracking resistance	Max. stock temperature

NOTE: Where "max. stock temperature" is recommended, reference is made to temperatures in the range of 550 to 600° F. In every case, however, maximum or minimum stock temperatures are those consistent with the quality desired. The choice of mold temperatures must be qualified by considerations of cycle as well as quality.

nesses commonly encountered in the molding of polyethylene in the field today, it is strongly recommended that molders check their material temperatures rather than rely on indicated temperatures.

In addition to thickness, consideration should also be given to the distance the material must travel in a mold through a given cross-section. Large pieces having thin sections would obviously require higher temperatures than large pieces with thick sections or smaller pieces of the same section. In any case, the higher the material temperature, within limits, the better the quality of the finished piece.

Softer-flow material

Because increased plasticity is an effect of increasing the temperature, it is also possible to employ polyethylene materials with softer flow properties at lower temperatures. However, this effect can be achieved only within certain limits since flow is a function of molecular weight, and softer flow is likely to be obtained at some sacrifice of physical properties. It is therefore obvious that the use conditions of the end product will to a degree determine and often limit the softness of flow.

Throughout this discussion, it has been recommended that higher molding temperatures be used. This implies longer cycles, since the injected melt will have to cool longer. The molder must naturally weigh the factors of quality required and allowable rejects against the speed of operation in judging the economics of the particular job.

In many applications in which quality is not critical and no trouble is encountered in fabrication, lower injection temperatures are acceptable to obtain shorter cycles, where cycle time is limited by setting time. However, investigations of minimum cycle have shown that mold temperature, although having little effect on cycle at low injection temperatures, is an important factor at injection temperatures which are high.

Indications are that it may be possible to control cycle by controlling mold temperature. That is, even though high injection temperatures are used, running a sufficiently cold mold may keep the cycle almost to the level achieved with lower stock temperatures. Of course, this partly offsets the effects hoped for in using high injection temperatures. Since the cycle would be critical with mold temperatures in this range, more efficient cooling and control in the mold would probably be required, with consideration given to better coring and to refrigerated coolants. Low mold temperature, although affecting cycle considerably, seems to have an insignificant effect on most properties of molded polyethylene, but it does decrease shrinkage.

Since the properties of injection molded polyethylene products are to a great extent dependent on the temperature of the material being injected, and since experience has shown that material temperatures often run well below indicated cylinder temperatures, the molder should check the actual material temperature while on cycle (by some means such as a needle pyrometer) to determine if the melt is at the proper temperature for optimum properties.

This is especially important as the ratio of shot weight-to-rated capacity increases and as cycle times decrease. In addition, for every molding job there exists a minimum temperature (consistent with good performance), depending on cycle, shot size, and configuration, below which poor properties may be expected. Generally, it is best to run as hot as is practical since the optimum minimum temperature is difficult to determine accurately. Running at high temperatures may require an increase in cycle but these increases can be kept to a minimum by proper mold design and the use of coolants which are more efficient.

INJECTION MOLDING LINEAR POLYETHYLENES

Phillips-Process Resins

BY J. VIRGIL SMITH* and J. N. SCOTT*

Marlex[1] 50 polyethylene is a linear polymer made by Phillips Chemical Co. The material, with a minimum amount of branching, has a crystallinity of 93 to 95 percent. It has excellent chemical resistance, low permeability, and good electrical properties.

In order to produce quality molded items, due consideration must be given to molding conditions, particularly mold design, gate design, gate location, cycle time, and the injection molding machine.

In filling a cavity, the polymer molecules will tend to line up (orient) parallel to the direction of flow. The degree of orientation is increased by the use of a smaller gate, thinner walls, and cooler mold temperatures. In certain applications, radial orientation will produce a more usable part. However, generally, where warpage is a problem, the degree of orientation should be kept to a minimum. Marlex 50 resin set up at a higher temperature may give a faster cycle for some parts. Through nonuniform cooling, it is possible to obtain a part with varying degrees of crystallinity and density throughout the part. This variation in density will contribute to warpage.

Equipment and molds

Equipment: With the flow characteristics and high solidification temperature of Marlex 50 resin and proper gating of the cavity, a large number of quality moldings can be obtained on a rapid cycle with standard machines and conventional feeding devices. However, in close-tolerance molding, the use of weigh feeders is recommended. Using the starved feeding technique, it is almost impossible to pack the cavity, but for some moldings, the commercially available weigh feeders operate too slowly to permit rapid molding cycles.

Normally, no special equipment is necessary when injection molding Marlex 50. For color dispersion, however, a dispersion nozzle is recommended.

Mold design: Suggested recommendations for mold design that will aid in the production of uniform parts in the shortest possible cycle are as follows:

1. Sprue and runner system should be as short as it is possible to make.
2. Full round gates should be used. (See Table I, p. 670, Sec. D.)
3. Cavities, where possible, should be center-gated for uniform fill.
4. Gate land length should be kept to a minimum to minimize pressure loss and excessive heat build-up in the gate area of the mold.
5. If warpage is a problem, gate diameter should be 0.070 to 0.250 in. I.D., depending on the thickness of the part and the weight of the shot.
6. Where possible, a localized cooler should be placed opposite the gate.
7. A localized ring cooler is recommended around the sprue-bushing. (Items 7 and 8 place maximum cooling in the area of greatest heat build-up.)
8. The extremities of the cavities should be cooled by separate cooling channels containing circulating water with temperatures ranging from 80 to 200° F.
9. Spiral-type channeling with the water inlet near the center of the mold and the exit at the extremity has proved to be very useful in the molding of flat center-gated items.
10. Cavity surfaces should be polished if a glossy surface is to be obtained on the part.
11. Air, ring, or pin ejection mechanisms are satisfactory.
12. Threads and other slight undercuts can be stripped from a mold that is properly designed.
13. The use of submarine gates or hot-runner systems permits automatic molding.

Molding characteristics

See Table I, p. 670.

Molding conditions: Since the material does not absorb water, no predrying is necessary. The maximum possible injection pressure and injection speed are recommended for molding Marlex 50 polyethylene parts. The employment of minimum injection time (forward plunger dwell) is desirable in the elimination of warpage in the molded item. In thin-wall moldings, the use of minimum injection time will insure the production of a tough molding without embrittlement in the gate area due to packing. In the case of heavy-walled items, a greater injection time will be required to pack the cavities to prevent sink and void formation.

If the melt in the cylinder is kept hot too long, it degrades. Top safe temperature for 20-min. exposure is 575° F. (in absence of air).

The total cycle time is a function of part design, mold design and the injection molding machine. With a well-designed mold, fast cycles can be obtained with Marlex 50 polyethylene since the material sets up at a high temperature. The part can be removed from the mold soon after injection is complete.

Mold temperatures: The best reproduction of the mold surface is obtained with high mold temperatures.

In thick-wall items, the elimination of sink marks can be obtained by using a low stock temperature and long injection time through a relatively large gate (125 mils I.D.). The mold temperature may vary from a cold mold to a hot mold (70 to 225°

1) in direction of flow	20–40	20–45	20–60
2) perpendicular to flow	20–35	20–40	20–60

F.) depending on the part design. Actually, in selecting a mold temperature, several factors must be considered:

1) The thickness of the part to be molded: With thicker wall sections, higher mold temperatures are desirable.

2) The rigidity desired for the molded object: Low mold temperature results in some quenching of the polymer. This quenching or rapid cooling of the melt tends to reduce the crystallinity and thereby change the related Marlex 50 properties such as stiffness. This quenching effect is greater in thinner sections.

3) As mold temperature is raised, the ease of flow of the polymer into the mold is increased.

4) High mold temperatures require longer cycles.

Cylinder temperatures: Because of its higher softening temperature, Marlex 50 requires higher (50 to 100° F.) processing temperatures than branched polyethylenes. Surface gloss and flow improve as stock temperatures rise, but excessively high temperatures cause sink marks in thick sections.

Injection pressure: Marlex 50 requires 75 to 100% of the machine's maximum injection pressure, depending on the shape of the mold cavities, gate and runner dimensions, and injection-cylinder and torpedo dimensions. High pressures facilitate rapid filling of the mold, improve surface appearance, reduce shrinkage and warpage.

When molding sections in thicknesses less than ⅛ in., the pressure exerted on the material by the ram is 12,000 to 30,000 p.s.i. in standard cylinders; in thicknesses between ⅛ and ¼ in., the pressure is 8,000 to 30,000 p.s.i.; and in thicknesses over ¼ in., the pressure is 4,000 to 30,000 p.s.i.

Purging routine: Purging is necessary only when changing material, color, or after high-temperature operation. A low cylinder temperature minimizes time and material required to purge clean.

Ziegler-Process Resins

BY G. H. SOLLENBERGER*

and J. C. HOUSTON*

With a few variations, molding techniques for the higher-density polyethylenes parallel those used for the lower-density types. Some of the more important aspects are as follows:

1) *Polymers* in the melt index range of 1.0 to 9.0 are widely used for injection molding, producing parts having generally excellent properties and outstanding surface finish. Parts molded from materials of less than 1.0 melt index may display superior tensile strength, impact strength, and en-

* Technical Specialist, Market Development Section, Chemical Div., Koppers Co., Inc., Pittsburgh 19, Pa.

vironmental crack resistance, but such parts often have poor surface quality and may require considerably higher molding temperatures and pressures.

2) *Cylinder temperatures* may range from 300° F. for some applications to as high as 700° F. for the high-speed molding of thin-wall items. Basically, the cylinder heat should be sufficient to permit rapid filling of the mold.

3) *Injection pressure* and ram speed should both be as high as possible in order to fill the mold quickly.

4) *"Pressure dwell"* or *"ram forward"* time should generally be as short as possible, since "packing" the mold often results in a wavy surface around the gate and also increases the tendency to warp.

5) *Mold temperature* should be low, from 130° F. down to as low as 20° F. for extremely fast cycles and high-quality parts. If filling the cool mold should prove to be difficult at high cylinder temperatures and injection pressures, it may be advisable to use a polymer, which has a higher melt index, to open the gate and runner system, or to utilize an injection machine of sufficient capacity to handle the job. Dew collection on mold surfaces also limits the reduction of the temperatures of the mold.

6) *Gate design* follows usual plastics practice, and fan gates, pin-hole gates, and sprue gates have been proven satisfactory. Both high and low melt index polymers have been processed without difficulty by hot-runner and runnerless techniques.

7) *Warp*, resulting from the relatively high shrinkage of polyethylene, can be reduced by allowing a slightly longer cooling time in the mold. Post-molding warp can be virtually eliminated by the use of properly-designed cooling jigs and fixtures. In general, fast injection into a cool mold with minimum pressure dwell time will serve to minimize warp. Design including stiffening ribs perpendicular to the general surface reduces the tendency to warp.

8) *Mold shrinkage* varies from 2 to 4%, with more shrinkage appearing in the direction of the flow. Many factors may have a strong influence on part dimensions. For example, a cool mold or a quick quench upon removal from the mold will generally reduce mold shrinkage. Normally, the mold shrinkage increases with increasing cross-section and mold temperatures.

9) *After-shrinkage* of the magnitude of 2 to 4% may be observed if injection molded parts are subjected to elevated temperatures, such as 212° F. for 30 min., or 250° F. for 10 minutes. Preliminary data show that the *total* dimensional change (mold shrinkage plus after-shrinkage due to use exposure at elevated temperature) is usually in the 4 to 6% range. It is interesting to note that parts exhibiting low mold shrinkage have shown higher after-shrinkage, and vice versa. Naturally, allowance must be made for this in the case of assemblies which will be exposed to heat, especially if one part is exposed to heat and the other is not or if one part is higher-density polyethylene and the other is not.

INJECTION MOLDING POLYSTYRENE

BY ROBERT R. MOYER*

With the introduction of the first commercial styrene approximately 20 years ago, injection molding of the material was based on the equipment and the general molding techniques applied for the cellulosic plastics. By 1950, polystyrene had become the largest-volume thermoplastic to be converted by the injection molding process. Consistent with the rapid expansion in volume usage, fundamental study of material rheology and injection molding characteristics have been and continue to be conducted.

The effect of the latter work has been observed in the form of improved material end properties, conversion characteristics, and uniformity. For polystyrene in particular, injection molding machine development has embodied vastly improved rates of mechanical action, more efficient heater and hydraulic systems, increased capacity (1950—60 oz., to 1953—400 oz.) and supplied unique design features (e.g., direct multiple-nozzle small automatics and preplasticizers).

Obviously, the fundamental studies of both material and machines have required that the effect of mold geometry be overlooked or minimized if reproducible results of an accurate index of test values were to be developed.

Since commercial molding practice provides for mold geometries of unlimited variety and utilizes the "available" machine, some compromise with optimum polystyrene molding conditions must prevail.

Cylinder—temperatures: Table 1, p. 672, indicates typical heating cylinder settings for selected groupings of commercial injection machines. High and low (°F.) values are presented for each control zone. No center-zone values are listed for equipment up to 6-oz. capacity, although some commercial models offer this feature. Similarly either no value or Variac is listed for nozzle settings.

For machines in this smaller-capacity range, inclusion of a center-zone control and "off-on" nozzle heating will normally result in overcontrol of temperature with resultant over-ride of front-zone temperatures and alternate nozzle drooling or freezing. When extended nozzles or direct injection multiple nozzles are required, constant "input control" is preferred.

For equipment 8-oz. and up, a value of 450° F. has been chosen to emphasize the desirability of maintaining nozzle temperatures at a minimum of slightly above the true stock temperature. When extended nozzles or hot-runner tooling is involved, higher nozzle temperatures (500° F. or above) are required either to compensate for the added distance the polymer must travel or to reflect that the controlling temperature area is in the hot-runner system.

Several concepts and consid-

24 to 48	.090	.125	.04909	40	90	7	15	12	20	20	60
48 to 150	.090	.135	.04909	60	120	4	15	15	30	30	60

erations are important to the specific application of the value ranges in Table I, as follows:

1. Both the mold and the injection heating cylinder are heat exchangers which function as opposing systems, but which must achieve balance for economy.

2. Low mold tolerance for heat dissipation should be compensated for by use of minimum cylinder temperatures and optimum injection pressures.

3. With the exception of thick-section molding (above 0.150 in.) lower front-zone temperatures effect the most desirable plastication preparation and mold-fill characteristics.

Table II, above, is applied further to describe and relate molding conditions. Part-weight has been chosen in preference to full-shot weight since it allows a better definition of molding conditions. The low and high values for "cross-section" represent minimum piece part gage, exclusive of ribs or bosses.

Mold gate cross-section values are for single-gated parts. For parts weighing 16 oz. or over, the use of multiple gates is primarily dependent upon the shape of the part. Reductions in area of 30 to 50% are allowable with the use of more than one gate.

Cycle elements include both low and high values per second to reflect both actual practice and the variation which must result from differences in gage and geometry of parts of equal weight.

The majority of parts weighing 48 oz. or over are produced on preplasticating machines. Hence the mold-fill time, and often the plunger-forward time, are equal to or lower than for parts of considerably lesser weight.

The use of special equipment or tooling design must be related to a specific part design or requirements of production economics. Ball check nozzles, dispersion disks, and heaters of special design (e.g., polyliners) are of this nature and have proven their value, but are not absolute requisites for molding.

INJECTION MOLDING SPECIAL STYRENES

In addition to the standard or general-purpose styrenes which are injection molded by the techniques previously described, there are a number of "special" styrenes commercially available which require special molding techniques for the best results. The following discussion of these techniques and how they are to be used has been prepared by the manufacturers of each of the materials. These companies and their products are included: Bakelite Co. (C-11 styrene acrylonitrile copolymer and the TMD series); Dow (Styron special styrene series); Koppers (Dylene styrene family and Fibertuff glass-reinforced polystyrenes); Monsanto (Hi-Flow, LHA, Hi-Test, and Hi-Heat series); Marbon Chemical

Div., Borg-Warner Corp. (Cycolac acrylonitrile-butadiene-styrene multipolymers); and Naugatuck Chemical Div., United States Rubber Co. (Kralastic compounds, including Kralac H and Kralastic B, D, F, and J blends).

Bakelite

Special Bakelite polystyrenes include C-11 styrene acrylonitrile copolymer and family of impact-resistant materials. These are: a high-impact polystyrene, TMD-5151; an extra-high-impact polystyrene, TMD-2155; a high-heat-resistant high-impact polystyrene, TMD-5161; and a medium-impact polystyrene, TMD-8020.

The physical properties, molding characteristics, and heat distortion temperature of C-11 have been balanced to satisfy the requirements of the majority of applications. C-11 is more difficult to mold than polystyrene, but it is possible to use it in most molds designed for polystyrene by adjusting mold and cylinder temperatures, and sometimes gate size. Increasing speed of injection, using "starved feed," or using a preplasticator will often allow C-11 to be molded on polystyrene cycles. If a substantial increase in pressure appears necessary, there may be danger of over-packing and subsequent sticking in the cavity. It is then best to increase stock temperatures within the recommended limits. To attain the optimum heat-distortion resistance of C-11, it is advisable to use the highest permissible mold temperature and the fastest possible injection speed. C-11 is not compatible with polystyrenes and some other thermoplastics. Therefore, care must be taken to avoid contamination.

TMD-5151 molds in a similar fashion to standard injection molding grades of styrene.

For maximum surface gloss, higher mold temperatures than are generally employed in injection molding of the regular grades of styrene should be used. Optimum results are best obtained with mold temperatures ranging between 140 and 160° F., with a temperature of approximately 150° F. usually proving most satisfactory. Actual stock temperatures ranging between 390 and 490° F. are recommended for TMD-5151.

TMD-5161, a high-impact heat-resistant polystyrene, molds in a fashion similar to standard injection molding grades of impact styrene. Because it is a heat-resistant material, it has stiffer flow properties and is faster setting. Actual stock temperatures from 440 to 490° F. are recommended and best results are obtained with a mold temperature of 160 to 180° F. To obtain the optimum heat-distortion resistance of TMD-5161, it is advisable to use the highest permissible mold temperature and the fastest possible injection speed.

TMD-8020 molds more like the general-purpose polystyrenes than the other impact polystyrenes. Mold temperatures of 140 to 160° F. and actual stock temperatures of 390 to 490° F. are recommended.

Dow

BY GORDON B. THAYER*

Specialized formulations have been developed by Dow to provide molding materials with styrene as a basic monomer.

An extra-high-impact material, designated Styron 480, was recently introduced. This shock-resistant material has been formulated without sacrifice of heat distortion temperature, which is 185 to 192° F. In addition to toughness, it has good heat resistance and surface gloss. Its moldability and extrusion behavior are good and it is also being successfully calendered.

Styron 475 is a rigid thermoplastic material which has good impact strength combined with high percent elongation and somewhat lower modulus of elasticity than general-purpose polystyrene. A combination of high impact strength, high elongation, and medium-high modulus provides toughness which has been found to be suitable for many applications.

Styron 475 requires a mold temperature of 160° F. or higher to produce a lustrous surface. Generally, it is necessary to run the mold temperature at a point somewhat higher than the 160° F. temperatures.

The heat distortion temperature of Styron 475 is somewhat lower than that of general-purpose polystyrene, but it is sufficiently high to be satisfactory for most household appliances. This material has demonstrated excellent retention of impact strength and elongation upon aging. The material is not recommended for applications involving outdoor use or ultra-violet radiation.

Styron 700 has a heat distortion temperature which is considerably higher than that of general-purpose polystyrene as measured by A.S.T.M. methods. Although the heat distortion temperature of many articles molded from Styron 700 is likely to be greater than 212° F., the material is not recommended for prolonged or repeated boiling. It is recommended that Styron 700 be used for applications which require the highest heat resistance possible with injection molded polystyrene materials. Such parts should be annealed in order to obtain the maximum in heat and craze resistance in the finished products.

Mold temperatures should be generally above 180° F., although in some cases it is not practical to mold with the temperature this high. Mold and product design should be carefully examined if it is not possible to mold satisfactory pieces in molds at a temperature less than 180° F. High stresses are likely to be encountered if the mold cools, and annealing becomes extremely difficult if the molded part is highly stressed. A very long annealing time is required under such conditions in order to prevent distortion of the part during the annealing cycle. Furthermore, long annealing cycles result in greater tendency to warp, and, therefore, the annealing temperature has to be further reduced.

Styron 688 is a fast-flow, general-purpose polystyrene which has a heat distortion temperature approximately 10° F. below that of Styron 666. Other physical properties are about the same as those of general-purpose polystyrene.

Styron 689 is a newer and easier

* Plastics Technical Service, The Dow Chemical Co., Midland, Mich.

flowing formulation than Styron 638. The brilliant sparkle and freedom from haze add to the attractiveness of crystal parts molded with this material.

Styron 683 is a heat-resistant grade of polystyrene. It has a heat distortion temperature about 20° F. higher than Styron 666 and physical properties equivalent to, or better than, those of Styron 666.

Styrex 767 is a copolymer of styrene and acrylonitrile. It is a rigid thermoplastic which can be readily molded.

Before molding, drying of the material can be accomplished with air-circulating ovens and either infra-red or electric resistant-type heaters. Drying for 1 to 2 hr. at 170 to 190° F. is recommended. It is imperative that the heating cylinder be completely purged of all other thermoplastic materials before molding Styrex 767. Normal range of cylinder temperature is about 400 to 550° F. In general, these temperatures will be 50 to 75° F. higher for Styrex 767 than for general-purpose polystyrene employing comparable machine pressures. Controlled mold temperature is an important consideration in the molding of Styrex 767. If mold temperatures in the region of 170 to 190° F. (or higher) are used, the moldings will exhibit maximum heat resistance and minimum tendency to craze.

Koppers

BY R. P. McLANAHAN*

The Dylene[1] polystyrene family offered by Koppers Co., Inc., includes normal polystyrenes, as well as modified formulations such as high-elongation (high-impact) polystyrenes, medium-elongation polystyrenes, and a group of heat-resistant polystyrene materials.

One recent addition to the family of normal Dylene polystyrenes is Type 2, developed especially for the fast molding of very thin, large-area sections, e.g., disposable containers, cups, tumblers, vials, etc. Type 2 offers good clarity, ease of flow, moderately fast setup, and freedom from sinks and waviness.

Dylene 3 is a general-purpose material combining good flow and set characteristics with physical properties and heat resistance intermediate between the easiest-flowing formulations and the improved heat-resistant types of polystyrenes. It is best suited for molding parts of medium thickness.

Dylene 4 combines easy flow for rapid filling with fast setup and mechanical strength properties approaching those of the medium-heat-resistant polystyrenes. It is used for heavy-wall and mixed thin- and thick-section molding. Dylene 7 offers good flow and fast set characteristics.

Dylene 8 is a heat-resistant type polystyrene for molding and extrusion purposes. It offers high heat resistance, tensile strength, and flexural strength with uniform moldability. These properties are also retained in Evenglo[1] polystyrenes, a series of specially pigmented materials, that are highly resistant to yellowing, and are used primarily in lighting applications. Improved Evenglo polystyrenes with increased light stability, known as the PL-color series, were recently introduced.

The high-elongation (high-impact) polystyrenes include: Dylene 200, an easy-flowing type which exhibits improved surface gloss and weld appearance and is especially adaptable to large-area, thin-section molding; Dylene 708 which has superior electrical characteristics, particularly at high frequencies, and low moisture absorption; and Dylene 800, an improved heat-resistant material.

In the medium-elongation series, Dylene 30 and 80 offer a property range that falls between the normal polystyrenes and the high shock-resistant type materials. They both possess excellent surface gloss and good weld-line appearance. Dylene 80 is used where higher heat resistance is required.

Cylinder temperatures: Cylinder temperatures for the various Dylene polystyrene formulations may range from 350 to 600° F. Usually, those materials possessing higher heat resistance will require higher cylinder heats and injection pressures.

Cylinder temperature settings for Dylene 8, for example, will run 30 to 50° F. above those used for general-purpose polystyrenes. Molding conditions for Evenglo polystyrenes will parallel those used for Dylene 8. However, with the PL-color series, cylinder temperatures above 540° F. should be avoided.

High-elongation and medium-elongation polystyrenes usually mold at lower cylinder temperatures than their corresponding formulations in conventional polystyrenes. Both classes of polystyrene formulations are resistant to scorching as long as exceedingly high cylinder temperatures, or prolonged exposures, even at low cylinder temperatures, are not maintained.

Cylinder heats and injection pressures are also dependent upon a number of other factors, such as the type of gate, runners, and sprue design used, as well as machine capacity and the particular shape and size of the part or parts to be produced.

Mold temperatures: Mold temperatures of 140 to 180° F. will yield parts with the best surface gloss and mechanical properties. Mold temperatures below 140° F. generally produce parts with a satin or matte finish. Excessively cool mold temperatures may result in flow lines, weak unsightly welds, as well as loss of mechanical properties. When working with Dylene 8, mechanical strength is improved by high mold temperatures, preferably with a cooling time allowed which is sufficient to permit molding stresses to relax while the piece is in the mold.

Predrying: Normally, it is not necessary to predry Dylene polystyrenes before injection molding because of their low affinity for moisture. However, when polystyrenes are subjected to a very damp or humid atmosphere in storage, or shipped in extremely cold weather, moisture may condense on the surface of the pellets or particles upon exposure to the warmer or more humid atmosphere of work rooms. Dylene polystyrenes may be predried be-

* Technical Coordinator, Chemical Div., Koppers Co., Inc., Koppers Bldg., Pittsburgh 19, Pa.
[1] Trademark of Koppers Co., Inc.

ore molding by use of a hopper drier or by placing in an air-circulating oven in trays.

Purging routine: Both conventional and modified polystyrenes are readily purged from injection molding machines by the standard purging procedure.

Handling: None of the various types of polystyrene pellets available require specialized methods of handling. However, care should be taken when opening bags or drums of the material to prevent contamination.

Glass-Reinforced

BY E. Y. WOLFORD*

Fibertuff[1] polystyrene Type 1-56 is a recently improved type of glass-reinforced styrene with increased tensile and impact strengths and hardness. It is expressly intended for injection molding. Hence, it carries an appropriate quantity of an effective lubricant to promote ease of injection molding. It is not intended for compression molding or extrusion into pipe or sheet.

Fibertuff polystyrene Type 1-56 is furnished in pellets of approximately ⅛-in. dia. and ½-in. length. This has been found to be the optimum length since shorter glass fibers will not felt easily in the molded piece and will weaken it, whereas longer fibers suffer excessive breakage when passing through the gate of an injection mold. The glass fiber content is 35 ± 2½% by weight. Experience has indicated that a content of 65% improved heat-resistant type polystyrene lubricates the glass fibers sufficiently so that 40 mil-dia. pinhole gates can be used successfully. However, as two separate substances are present in heterogeneous mixture, the glass-reinforced styrene should not be confused with single-phase or homogeneous plastics such as nylon. Nor, since the glass increases both dielectric constant and dissipation factor, is it to be regarded as a material for electrical applications. The glass fiber is slightly hygroscopic and predrying of pellets is desirable but not necessary.

Compositions of lower glass fiber content and higher polystyrene content can be made by simply drum-tumbling the Fibertuff polystyrene pellets with normal or modified polystyrene pellets. The polystyrene pellets used for mixtures should always be of the improved heat-resistant type such as either Dylene[1] polystyrene Type 8 or Dylene modified polystyrene Type 800. Such admixtures, when injection molded, give uniform dilution of the glass fiber content; the fibers become poorly distributed only when reduced to less than 10% in content. Mixtures with modified polystyrene give very interesting impact-strength results. Point shocks appear to be resisted by the glass fibers. Gross shocks appear to be distributed throughout the molded structure by the modified polystyrene.

Dry coloring can also be accomplished by drum-tumbling, but, whenever the technique is used, the tumbling time should not exceed 15 minutes. Longer duration causes the glass fibers to fray out from the pellets, resulting in a tufted appearance in the surface of the molded pieces.

Fibertuff polystyrene pellets should be handled with gloves to prevent irritation and slow-healing dermatitis from glass fiber spicules. After molding, pieces can be touched with the bare hand without harm. In some cases, pieces have been dipped in aqueous destaticizer baths to remove surface spicules.

Molding conditions

Molds for Fibertuff polystyrene preferably should be hard-chrome-plated for abrasion resistance, although for molded pieces where surface appearance is unimportant, such plating can be ignored. Experience indicates that hard chrome plate may need renewal after 100,000 shots or less. In any case, flash chrome plate should be avoided. It merely promotes pitting by galvanic action. Hard chrome plate should be put over well-burnished copper and nickel under-coats to minimize pinholes.

The chief advantage of Fibertuff polystyrene, over and above enhanced mechanical strength, is its low mold shrinkage (ordinarily 0.001-0.0015 in. per in.) which allows molding to close tolerances. This factor, coupled with the rigidity, moisture resistance, and dimensional stability of the glass-reinforced styrene, makes the material especially useful for large-diameter, narrow width, close-tolerance reels, for spools and cage-type fan rotors, and other assemblies where the fit must be especially close and reliably permanent. For such pieces, the higher bulk factor (3.0 to 3.5) should be remembered when choosing the capacity of machine in which to run the mold. Maximum injection pressure is usually desirable to insure quickest fill of cavity. Cylinder temperatures between 450 and 600° F. have been found to give cycles of 120 to 30 seconds. Exposure to elevated temperatures for long periods should be avoided to prevent scorching. Of importance also is keeping the machine on cycle without interruption. However, pinhole gates have not been found to cause scorching of the polystyrene.

As there is no way to obtain bridging of glass fibers across weld interfaces, welds will have only the strength of normal polystyrene. Hence, welds should be minimized in design. In addition, holes should be frequently drilled by carbide-tipped tool rather than molded around cores. The same adhesives which serve for normal polystyrene are suitable with Fibertuff polystyrene, but such joints are not glass fiber reinforced.

Monsanto

BY ROBERT R. MOYER*

Recent changes in the Lustrex line include the addition of new polymers, the revision of formulations, and changes in nomenclature for several grades. The additions and changes reflect the rapid volume increase in extruded sheeting, the trend to automatic molding, and the continued expansion of packaging applications. The line includes impact, heat-resistant, and general-purpose grades.

General-purpose grade (un-

* Manager, Plastics Technical Service, Chemical Div., Koppers Co., Inc., Koppers Bldg., Pittsburgh, 19, Pa.
[1] Trademark of Koppers Co., Inc.

* Technical service manager, Styrene Molding Materials, Plastics Div., Monsanto Chemical Co., Springfield 2, Mass.

modified styrene): Current types are Hi-Flow 55, Hi-Flow 66, and Hi-Flow 77. Hi-Flow 66 is a new polymer of medium-flow grade. It is available as a colorant blend, crystal, and in transparent, translucent, and opaque colors. The nominal heat distortion is 176° F.

Hi-Flow 77 is the new nomenclature for Lustrex L. Fast setup rate, with relatively good flow and moldability, characterize this grade.

Hi-Flow 55 is used primarily as a colorant blend and pelleted crystal. It was originally developed for thin-wall and automatic molding requirements. Polymer molecular weight control results in a sharp softening point upon plastication and improves both the rate and uniformity of material heating in the injection cylinder. The product's nominal heat distortion of 165° F. was set to allow satisfactory use performance and to avoid the development of high residual strain due to rapid setup in thin-wall sections.

Impact-grade Lustrex (rubber-modified): To supplement LHA and Hi-Test 88, new polymers known as Hi-Test 88-A and Hi-Test 88-B have been added to the line. Hi-Test 88-A has improved toughness and higher elongation at yield. Currently it is available only as a colorant blend. Hi-Test 88-B has improved toughness, is a natural white and highly translucent base resin, and is available as a colorant blend, natural pellet, and in process colors.

Processing and physical property characteristics ascribed to Hi-Test 88 in the following paragraphs also apply to Hi-Test 88-A and Hi-Test 88-B.

Lustrex Hi-Test 88 is a tough, rubber-modified styrene for injection molding. It is available in a wide color range of pelleted translucents and opaques. A special natural (milky white) formulation also is available for dry coloring.

Elongation values are in the range of 20 to 25%, giving it 10 to 15 times the elongation of general-purpose styrene. Because of this improved elongation, less taper is required in the mold and in many cases shallow threads can be stripped. Impact values range from 50 to 500% higher than would be the impact values for general-purpose styrene.

In addition, Hi-Test 88 has excellent resistance to repeated flexing—a property which, when combined with its ultimate elongation and impact properties, gives the material an all-around toughness. In many cases it is this special feature of toughness that is required rather than any other individual property. These properties make Hi-Test 88 especially suitable for many applications.

Impact and elongation properties of all rubber-modified styrenes vary with the amount of orientation developed in the molded item. Maximum impact is obtained at lower injection cylinder temperatures, resulting in maximum orientation.

Excellent gloss can be obtained from Hi-Test 88 using conventional molds for styrene, with mold temperatures in the range of 140 to 160° F. Its mold shrinkage is comparable to that of general-purpose material. No special handling is required.

The heat distortion temperature of Hi-Test 88 has been reduced, compared to previous Monsanto impact formulations, to provide improved moldability. Its present heat distortion of 168 to 173° F. is sufficient for most applications. For special applications requiring improved heat distortion, Monsanto offers one other high-impact material, Lustrex LHR. Slightly higher cylinder and mold temperatures are required. The heat distortion range is 188 to 194° F.

Lustrex LHA, a medium-impact, rubber-modified grade, is especially suitable when additional toughness over general-purpose styrene is required. Its impact strength is about twice that of general-purpose material. Because of its added toughness, it is easily ejected when molded in thin-section and in deep draw parts with limited draft.

LHA is recommended for jobs formerly molded of general-purpose material to eliminate fracture on die ejection and in subsequent assembly operations to reduce breakage.

For die design, draw clearances of less than one-half degree taper per side have been used. The material can be molded readily at cylinder temperatures in excess of 600° F. If it is held too long at such temperatures, however, thermal breakdown occurs and the molded part loses impact strength. This condition is apparent when dark streaks appear on the surface of the part.

Hi-Heat 99 and Hi-Heat 99-A are offered as improved heat-resistant Lustrex compounds. Hi-Heat 99-A, a new polymer type, is particularly suited to extrusion and may be postoriented. This product is formulated for both injection and extrusion processing. Hi-Heat 99-A is available as crystal and Hi-Heat 99 as colorant blend, and in crystal and process colors. Subject to part design and the degree of residual strain, molded parts may withstand boiling water without deforming.

Formulations for this product, both for molding and extrusion, include colorant blend, crystal, transparent, translucent, and opaque colors. Machine heater settings, as related to general-purpose styrene requirements, should be 25 to 50° higher on all bands. Whenever possible, the front or nozzle band should be increased the minimum necessary to control mold-fill characteristics.

Maximum booster settings short of "pack" condition are preferred to higher injection pressure.

Cycolac Terpolymers

BY C. R. HOLT*

A multipolymer based on acrylonitrile, butadiene, and styrene, Cycolac is not a blend of resins, rubbers, or plasticizers but is a single material of uniform molecular structure, available in several different forms: white powder for calendering and solution work; natural-color (light translucent tan) pellets for extrusion and molding; pigmented pellets for extrusion and molding.

When injection molding Cycolac, it is preferable to predry the material before molding. Recommended procedures are as follows:

Type of equipment: Oven or

* Technical Service Mgr., Marbon Chemical Div., Borg-Warner Corp., 7165 Chicago Ave., Gary, Ind.

infra-red lamps; drying time, 1 hr.; drying temperature, 150 to 175° F.

Hopper driers are also advantageous for driving off surface moisture and for prewarming the resin. Drying temperature, when using the hopper dryer, is 200° F.

Equipment and molds

Equipment: In the injection molding of Cycolac, shot size should normally not exceed 50 to 60% of the capacity of the machine. As the part size increases, or as surface area becomes greater, the ratio of capacity to shot size should be increased and the gating made more generous.

Mold design: Molds for Cycolac should be constructed along conventional lines, bearing in mind the usual need for high pressures, generous runners, and large gates. Details such as internal ribs help the plastic to flow to the far ends of the cavities. Runners and mold surfaces should be highly polished for best flow of material and fine finish on the molded piece.

Runners: All multi-cavity molds should be designed with the shortest possible runners and with gates balanced for uniform fill of each cavity. Long major runners should be extended slightly beyond the furthest secondary runners to act as cold-slug traps ahead of the cavities. In some instances, a hot-runner-plate construction is helpful. Water-coring should be designed to keep runners as hot as possible.

Gating: Proper gating is very important for producing good-looking parts from Cycolac. Pinpoint gates are not recommended and restricted gates are normally satisfactory only for small parts of low surface area. In this type of product, a small gate should feed the plastic stream against a target wall or insert in the cavity to break up the flow pattern and prevent jetting. Excellent surface finish and appearance are obtained in this manner.

Gates must be rounded and streamlined, preferably widened at the cavity end and fed from deep runners so that hot resin flow is not hampered. Large gates should enter a heavy section of the part, not flush with a finished surface, to promote rapid fill and continuous steady flow from thick to thin areas. Gating on a finished surface may easily produce a blemish at the gate area.

Sprue-gated or center-gated parts which cannot take a cold-well will often show blush-rings or wave-marks around the gate. These should be run with a reverse-taper nozzle and/or with heater bands on the nozzle in order to prevent stiffening or chilling of the resin at the nozzle-end between shots. Disk or diaphragm gating into a small natural opening of the part is usually satisfactory, with the gate and cold-slug machined, punched, or bored out during finishing. Edge gates on thin sections cannot be opened up except by fanning out the gate along the edge or by deepening the gate over onto the surface of the section. Any deepening of the gate into a rib or structural part on the bottom side will help the flow. On parts of considerable surface area which must be edge-gated, the gate should be located on the longest side in order to provide the shortest possible flow across the face of the piece.

Multi-gating a large part will obtain rapid fill at lowest temperatures and pressures in the shortest cycles. This can be done into a large natural opening of the part (where an overly-large diaphragm gate is undesirable), or can be conventionally edge-gated. Principal deficiency of multi-gating is the creation of extra weld lines. With Cycolac, this is not too much of a problem, provided high mold temperatures are maintained and the weld areas adequately vented. All gates on a multi-gate part should be balanced to obtain uniform fill with the final weld taking place at the bottom edge or far edge.

Molds should be vented adequately in all areas to prevent gas burning, especially at welds.

Molding conditions

Molding technique: Molding of a new part should be started with low cylinder temperatures (380 to 400° F.), hot mold (170 to 180° F.), largest possible gate and nozzle, maximum pressure, and long cycle. A trial air-shot should be taken to inspect the plasticity, color, and appearance of the plasticated resin. The rope should be smooth, glossy, and nonporous, without lumps, particles, discoloration, contamination, or large blisters. After locking nozzle against bushing, temperatures should be gradually increased until complete fill is obtained (preferably not over 475° F. on the cylinder). Cycle time can then be reduced to the point of short-shots by first reducing injection time, then total time. Further reduction in cycle and in pressure can often be achieved at this point by enlarging the gate and runners. Inability to get full shots on a long cycle over a temperature range of 400 to 500° F., or the necessity of increasing molding temperatures more than 50 to 75° F. over that of the air-shot, very definitely indicate the need for larger gating.

Mold temperature: Mold temperature control is important for obtaining maximum gloss and a surface free of drag marks. Molds that are too cold will give short shots, strained parts, smear marks, dull finish, and weak welds. Too hot a mold will cause distortion of the part, sinking, and flashing, and will extend the freeze phase of the cycle excessively. The mold should be carried as hot as possible without involving these latter defects.

Purging routine: The press should be purged of Cycolac as soon as possible after a run is completed. When appreciable operational delays occur, the cylinder should be emptied of Cycolac. For purging, cylinder heats should be reduced to 400° F. or less and the cylinder purged at reduced pressure with a slow ram, using a viscous plastic such as acrylic or high-impact polystyrene. Temperatures should never be raised in purging Cycolac.

U. S. Rubber

BY WILLIAM J. COUGHLIN*

Kralastic[1] is a family of plastics in the category of acrylonitrile-butadiene-styrene polymers.

Hopper drying or oven drying is recommended when optimum gloss and appearance are desired. No special equipment is required. However, Kralastic is also being

molded successfully without drying. The granules can be dried sufficiently under conditions ranging from 4 to 6 hr. at 140° to 45 min. at 190° F.

In moldings where the injection pressure requirements are critical, external lubrication (36 gm. of zinc stearate/100 lb. Kralastic) is often required to reduce the pressure loss sustained in compacting the granules in the rear of the cylinder. The need for external lubrication must be considered on an individual job basis, with the definite molding machine and mold being considered.

Molding conditions

Kralastic can be injection molded on standard equipment, including machines equipped with preplasticators. Kralastic does not have a sudden critical melting point, nor does its consistency ever approach the state of water-like liquid. Kralastic can be molded over a wide temperature range (350 to 600° F.), with stock temperatures between 400 and 475° F. resulting in the best combination of physical properties and cycle times. Generally speaking, stock temperatures should be kept as low as possible, often determined by a visual inspection of the molded piece. However, there will be occasions when raising the stock temperature will result in improved knit lines and consistency of impact strength throughout the molded piece. Raising the stock temperature will slowly degrade the physical properties, but will not result in a sudden degradation.

Kralastic can be allowed to sit in the cylinder for a nominal length of time, and does not have to be purged during short shutdowns. Kralastic can be left in the cylinder indefinitely when the heat is turned off. Inspection of an air shot or a short shot will often help determine whether excessive conditions are being used. An air shot will indicate if the desired uniformity of consistency and color is being obtained, or whether the material is being overheated by excessive cylinder or nozzle temperatures. Abnormally rough leading edges in short shots usually means that the stock temperature is too low and that weld lines will not knit properly. Checking the runners may also be a help in detecting cold slugs or brittleness.

Critical flow situations, such as large, thin sections, unusually large shot size, large number of cavities, etc., may require cylinder temperatures of 500° F. or higher. If satisfactory parts are not obtained after gradually raising the stock temperature to the 500° F. range, maximum physical properties and minimum cycles will probably be obtained by: a) opening the gates and b) enlarging the runners. Of course, before such major changes are made, consideration should be given to the possibility of using a larger molding machine and/or preplasticators, and checking to see that all present equipment is working properly.

Maximum finish can be obtained by high mold temperatures (160 to 200° F.) and highly polished molds. The longer cycles introduced by high mold temperatures can often be reduced by the use of jigs, cooling baths or lower stock temperatures. When finish is not important, Kralastic can be run with cold water on the mold. Consideration should be given to the proper cooling of pins and core plugs. Warpage and cycle times can often be reduced by an air blast on the extremities of the mold that cannot be internally cooled.

Gates and runners

Molds for Kralastic have been designed with a wide variety of gate sizes (0.30 in. round to 1.875 by 0.125 in.). Large gates are generally recommended with the shot size, wall thickness, and the individual flow requirements the determining factors (see Table I, above). Restricted gating[2] has been used successfully but is not generally recommended. When short shots are obtained with restricted or pinpointed gating, the turbulence at the restriction point may require a lower, rather than increased, ram pressure. When positioning gates, consideration should be given to avoiding the placement of weld lines at locations where appearance or impact strength are critical.

Full-round runners (3/16 to 1/2 in.) are recommended; a trapezoidal design is the next most effective. Nozzle sizes from 1/8 to 1/2 in. have been used with 3/16 to 5/16 in. sizes the most common.

INJECTION MOLDING VINYLS

BY G. G. ROTHMAN* and BILL WILLIAMS**

The emergence of a sound body of knowledge on the equipment and techniques necessary to mold vinyls successfully has made it possible for today's molders to take advantage of the unique properties of vinyl without encountering any of the thermal stability difficulties of past years. As a result, there has been a noticeable growth in the use of vinyl in the molding field.

Elastomeric vinyls, compounded from vinyl resin mixed with plasticizers, fillers, colors, lubricants, and light and heat stabilizers, are commonly available in the form of granules, cubes, or powders. The granules and cubes need a minimum of processing heat and working before molding. They have a significant heat history. The powders, on the other hand, have practically no heat history and are used for producing articles with more residual heat and light stability than those produced from granules or cubes. These powders, however, require more shear and working before injection molding in order to produce a satisfactory molded piece. Common practice when molding

If round, diameter, mils	25-40	30-125	250-500
land length, mils	60	60-250	Small as possible
If rectangular, depth, mils	—	20	250
width, mils	—	60	500
land length, mils	—	60	Small as possible
E. Shrinkage allowance, mils/in.	Without annealing 10-30	Without annealing 10-30	Without annealing 4-6

the powders is to use oversize cylinders, dispersion nozzles, and often preheating of the powders to secure proper molded quality. Since it is more difficult to achieve high surface gloss when molding from powder, the technique is used more often in applications in which finish is not too important.

Rigid vinyl is the term applied to modified polyvinyl chloride and *unplasticized vinyl* refers to polyvinyl chloride which has been compounded only with stabilizer, lubricant, and color. The processing of unplasticized vinyl is not a simple matter and the incorporation of modifiers, e.g., rubbers, fillers, and often small amounts of plasticizer, to produce rigid vinyls, has been done in the interest of increasing the processing ease and/or impact resistance. In general, however, the inclusion of these modifiers results in lowering the chemical resistivity and the heat distortion temperature slightly. Unplasticized high-molecular-weight polyvinyl chloride is difficult to injection mold by conventional methods. Heat alone (below the thermal decomposition point) does not reduce the viscosity sufficiently for the material to flow easily. The flow curve of unplasticized and rigid vinyls seems to be slightly thixotropic in nature and the employment of shear and agitation immediately prior to the injection molding operation aids considerably in reducing the viscosity of the material and thus producing strain-free, homogeneous molded parts. As the Durometer hardness of vinyl compounds increases so do the injection molding temperatures and pressures.

Handling and equipment

Predrying: Since moisture absorption of vinyl is extremely low, predrying is not necessary.

Handling: Normally, no difficulties are encountered in molding vinyl as long as time and temperature recommendations are followed. However, considerable HCl gas can be evolved if the compound decomposes due to exposure to excessive temperatures for a period of time.

Special equipment: Normally, no special equipment is needed or used when molding vinyl. However, in the case of molding vinyl dry blends, a breaker plate nozzle may be used to aid in dispersing color pigments.

Cylinders: It is desirable to operate injection molding machines at less than rated capacity when running vinyls. A figure often used is about 75% of rated capacity, which includes sprue-bushing, runners, and cavities. Some molders have overcome this necessarily lowered capacity by replacing the standard cylinder with an extra-capacity cylinder. This method allows for a larger shot size and, if properly used, can actually result in longer runs before discoloration of stock is noticed. The temperatures used in an extra-capacity cylinder are normally lower than in a standard cylinder, since it takes the stock longer to travel through and therefore gives it more time to become plasticated.

Recommended materials of construction for cylinders and spreaders are carbon steel (may be used with very accurate

cylinder temperature control), chrome-plated steel, and Hastalloy C.

Plastication: The need for proper plastication is more important with vinyls than with many other molding materials. The rather low thermal conductivity of vinyls coupled with closeness of vinyl's flow temperature to its "thermal decomposition temperature" make necessary the use of improved plasticating methods.

The use of plasticating aids, such as small nozzles, restricted gating, longer cylinders, improved torpedoes, and preplasticating units, all contribute to easier molding of vinyl compounds. The screw preplasticating type of machine does an excellent job in plasticating PVC since the mechanical working and agitation of the material helps to distribute externally applied heat uniformly through the mass as well as to build up frictional heat. This results in lower cylinder temperature and, consequently, less exposure to the time-temperature cycle which is so important with vinyls. Restricted gating and small nozzles allow some reduction in cylinder temperatures since both methods generate frictional heat quickly by restricting flow and increasing velocity of flow.

Runners: In designing the mold, account should be taken of the fact that vinyls form a rather viscous melt instead of a fluid one. When the melt contacts the relatively cold surface of the mold, a vinyl skin is quickly formed in the sprue-bushing and runners. This effectively cuts down the runner area, and makes it necessary to increase the ram pressure in order to fill the cavity. With undersize runners, it may be very difficult, if not impossible, to fill the mold cavities completely. In practice, it has been found that full round runners, from 5/16 to 1/4 in. in diameter, are most satisfactory. The sprue-bushing itself may taper to 3/8 to 1/2 in. in diameter.

An important feature in runner design is the "liberal" use of cold-slugs or cold-wells to trap out the leading edge of chilled material flowing through the runners. If this material enters the mold cavity, it can cause many appearance defects, such as flow lines, weld lines, peel, etc. These cold-slugs should not only be placed at the end of the main runner, they should also be placed in the feed runners, just before the gates.

Gating: See Table I, p. 679, Sec. D. The subject of gating is a controversial one. Advantages and disadvantages can be found for all of the types which have been used. However, the simplest gate for molding vinyl is a pinpoint gate in the neighborhood of 30 mils in diameter. Its use generally promotes a better surface gloss on the molded articles because of frictional heat build-up, there is no degating problem, and there is less tendency for shrinkage of the molded piece at the gate section.

Normally, gates should be full round and as small in diameter as possible, but not so small as to create the need for excessive pressures to fill the mold cavity. For a larger molded piece, too small a gate would result in an inferior molding due to the creation of excessive mold-fill time.

Molding characteristics

See Table I, p. 679.

Special techniques: In the molding of vinyls, it is of prime importance to keep the stock moving through the cylinder. Consequently, during start-up, occasional purge shots should be taken so that material does not remain in the heated cylinder too long. On shutting down, the heaters should be turned off and the cylinder "flush-cooled" to below 250° F. before the operator leaves the machine.

If the melt in the cylinder is kept hot too long, it degrades. Top safe temperature for 20 min. exposure is 320 to 360° F.

Molding temperatures: Vinyls are truly thermoplastic, yet they actually are quite viscous at molding temperature. This temperature may be quite close to the so-called "thermal decomposition temperature" of the compound being used. Actually this is a function of both temperature and time. The maximum advisable molding temperature of a given vinyl compound varies according to the length of time that compound is to be held at that temperature. This is not a straight line function. While a vinyl compound may be held for hours at its optimum molding temperature, a temperature rise of as little as 10° F. above optimum may, in some cases, reduce the compound's stable time to a few minutes. This characteristic of vinyl compounds is the reason that flash-heating methods, such as restricted gating, are generally used. This time-temperature sensitivity varies over a wide range with commercially available molding compounds. In general, the harder the compound the less the spread between flow temperature and "decomposition temperature." Because of this, and the fact that vinyls have low heat conductivity, it becomes important to modify injection techniques in order to accomplish good results.

Purging routine: Purging becomes necessary when the compound starts to discolor. The compound being molded can be used for the purging, but a harder vinyl is generally more applicable. Polyethylene has also been used. When carbonaceous material breaks loose from the cylinder wall and enters the mold cavity, the cylinder should be pulled and manually cleaned.

For a clearer understanding of the recommendations contained in the individual articles that follow on the compression and transfer molding of specific plastics materials, this introductory section covering basic over-all techniques has been prepared.

INTRODUCTION TO COMPRESSION MOLDING

BY CHARLES E. MARKHOFF*

Since thermosetting molding materials are not fully reacted when they reach the molder, the application of heat and pressure in the molding operation serves to complete the polymerization reaction. Compression, plunger, or transfer molding are the methods most commonly used to soften and to shape thermosetting molding materials, as well as to cure these materials.

In compression molding, the material, either loose or preformed, is placed directly into the open mold. As the mold is slowly closed, the material becomes plastic and is forced into all parts of the mold. The mold is kept closed for the time required to cure the part.

Types of molds

There are four general types of compression molds: 1) flash; 2) positive; 3) semi-positive; and 4) landed-positive. (See Figs. 1 and 2, right, and Figs. 3 and 4, p. 682.) The subcavity type, Fig. 5, p. 682, is a variation of type 4.

The truly positive-type mold provides a tight fit between the force and cavity. Almost no material escapes during molding and full pressure is maintained on the material. Since excess material cannot escape, this design is not widely used. Instead, the semi-positive and landed-positive variations find greater acceptance. These designs permit the use of multiple-cavity molds since the excess material is free to escape. However, the two halves of the mold telescope to some degree; this telescoping maintains pressure on the material during the last of the closing cycle. Consequently, these designs are usually modified with sprues or flutes in the telescoping forces to permit easier escape of excess material.

Flash molds permit the escape of material between the cut-off lands as the mold closes. The pressure on the material is less with this type of mold. A greater excess of material must be used; slow press closing is recommended, as is also the use of material having the proper plasticity. The initial cost is also less.

Application possibilities

Compression molding is especially applicable to the molding of large-area, deep-draw parts. Radio and television cabinets, instrument housings, trays, and similiar large parts are molded by this method. The size of the article which can be molded is limited only by the tonnage and size of the available press equipment. In addition to large articles, compression molding is used to good advantage in the large-scale production of simply designed articles such as buttons, closures, tableware, radio tube bases, electrical wiring devices, and similar products. On these smaller parts, multiple-cavity molds and/or automatic compression molding techniques have made important production savings possible.

Compression molding is not normally recommended for intricately designed articles containing undercuts, side draws, small holes, and inserts. The flow of the material under high pressure may distort or break pins and dislodge inserts. Such parts are usually made by transfer or plunger molding. However, the use of electronically preheated powder in compression molding appears to be overcoming some of these disadvantages. Less pressure is required to mold an article using preheated powder than using a preheated preform. This may broaden the application of compression molding.

Transfer molding

Transfer or plunger molding is the term applied to the process of molding articles by injecting the

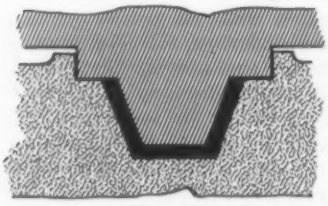

Fig. 4: Landed compression mold of the positive type

molding material into the closed hot mold in a hot plastic state from an auxiliary chamber. There are two methods which fall under this classification: transfer or pot-type transfer and plunger or auxiliary ram transfer.

In both methods, the material is forced from an auxiliary chamber to the closed mold where it is kept until the part has cured. Pot-type transfer has been largely replaced by the plunger method of molding. Plunger molding has several advantages to offer over compression molding. As mentioned previously, the filling of intricate molds or molds with long core pins or inserts is better accomplished with plunger molding. In addition, shorter molding cycles are possible with plunger molding. The loading time is shorter with plunger molding since fewer and larger preforms are used. These can be preheated more rapidly and efficiently and handling time is reduced. Shorter curing times are possible, particularly in thick sections. This is true because material is heated as it is forced through the gate. Volatiles are also permitted to escape through vents and clearances around movable pins.

The initial mold cost of a plunger mold is lower since deep wells are unnecessary and mold sections can be thinner than with compression molds. Easier finishing is also possible with plunger-molded articles since the flash should be quite thin or nonexistent. Gates can usually be made sufficiently small and so located that the removal is easy and inexpensive.

There are a number of disadvantages of plunger molding when compared with compression molding. The material left in the pot and runners is completely reacted and must be discarded. This loss is unavoidable and can represent a sizable percentage of the weight of the pieces molded. Another disadvantage is loss of mechanical strength with improved-impact materials containing fibrous fillers.

Plunger molds

Most plunger molds have been designed with the following conditions in mind: 1) minimum plunger pressure, permitting larger molding areas with the same clamping force, allowing 15% safety factor for adequate clamping; 2) smallest runners possible to prevent waste; and 3) smallest gates possible to minimize finishing operations and provide faster curing cycles.

In addition, individual hardened steel cavities and forces should be mounted in the chase and force plates. Runners and gates also should be hardened. A hardened-steel block insert for the gates is especially recommended. The center of the block at the bottom of the pressure chamber should also be a hardened-steel insert. All land areas should be ground and polished for maximum contact so that the material will not flash from the cavities and runners when the mold is closed.

Circular or square runners permit the use of lower plunger pressures. Runners should be as short as possible to avoid precuring the material. Larger diameter runners and gates are recommended in molding impact materials in order to preserve the impact strength. Larger diameter runners are also recommended for heat-resistant materials since the heat transfer is faster with a mineral-filled material than with a general-purpose material.

The gates should be located so that the removal may be accomplished easily by simple finishing operation. Generally, the cavity should be gated into a heavy section. Care should be taken not to gate the cavity directly opposite a mold pin or other protrusion. Such a design could cause flow lines and weld lines which mar the appearance and may decrease physical strengths. If possible, the gates should be located so that the entering stream of material does not directly strike a polished mold surface.

Proper venting is essential to successful plunger molding. Vents permit quick escape of air and gas. Vents should be located at the point which fills out last. This is usually, but not necessarily, the point farthest from the gate. Proper venting will permit rapid filling of the mold, give shortest cycles and cures and help avoid sticking and staining problems. Vents 2 to 5 mils in depth and $\frac{1}{16}$ to $\frac{1}{8}$ in. wide are common.

Miscellaneous factors

The success of a molding operation is not solely dependent upon the method chosen. Other important factors are: the proper selection of material; whether or

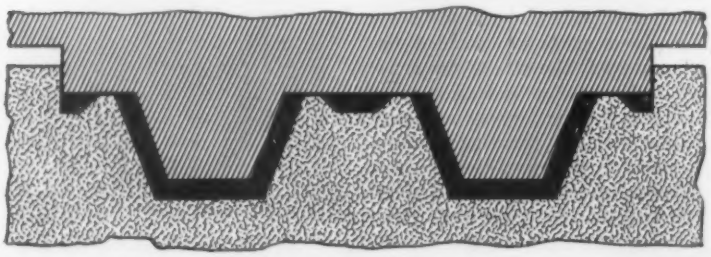

Fig. 5: Sub-cavity type compression mold

not to preform; type of preheating; whether to use an automatic operation; mold design; and, last but not least, the design of the article to be molded.

Good mold design must start with the design of the piece. With the emphasis being placed on automatic molding operations, this principle is more important today than ever before. In order for a molding operation to be completely automatic, the part must mold and be ejected without trouble every cycle. To achieve this type of operation, one must begin with the proper design of the part and follow through with the proper design of the mold.

COMPRESSION MOLDING ALKYDS

BY J. J. MOYLAN*

Continuing research on alkyd molding compounds has resulted in the development of many types since their introduction more than ten years ago. While the general characteristics of fast cure and low pressure requirements are common to all of these compounds, they may be divided into three different groups corresponding to physical form before molding.

Granular materials: The physical form of materials in this group is that of a free-flowing powder. Thus, these materials readily lend themselves to conventional molding practices such as volumetric loading, preforming, and high-speed automatic operations. These materials have found extensive use as high-grade electrical insulation, especially in the electronics field. Typical applications are television tuner segments, electronic tube bases and sockets, resistor housings, etc.

Putty materials: This group contains materials which are furnished in soft, putty-like sheets. They are characterized by very low pressure requirements (less than 800 p.s.i.) and find use in molding around delicate inserts and in special loading problems. The molder of these types customarily extrudes the material into a ribbon of a specific size which is then cut into preforms before molding. Putty materials have found widespread use in encasing electronic components such as capacitors, resistors, small coils, etc.

Reinforced alkyd materials: Among recent additions to the alkyd family are materials which combine the molding characteristics of polyester resins with the reinforcing action of fibrous glass fillers to attain very high strength. These materials have found widespread use in such applications as insulating brackets and bases, rocker rings, circuit breakers, heavy-duty coil forms, and similar applications where high strength and good electrical characteristics are important. In many cases they have replaced assemblies of metal and insulating materials. Recent developments in materials of this type include a compound having markedly superior handling characteristics. In addition, alkyd materials having small percentages of glass fibers, intermediate in strength properties and cost, are now available, as well as materials containing sisal and other fibers for reinforcements.

Within each of the three groups of alkyd materials described above, several distinct types are available. For example, some types are self-extinguishing, some have approval under military specifications, some have improved high-humidity performance. The manufacturers' literature on these materials should be consulted before selecting a material for a specific application.

Presses and equipment

Although full realization of the advantages of molding alkyds is best attained through the use of high-speed, lightweight equipment, nearly all modern compression presses are suitable for use with these materials. Some presses may be encountered, however, which are so slow that it is necessary to speed the ram travel by use of a high-volume pump or to decrease the amount of travel by mounting the mold on blocks to reduce daylight. Because of the low-pressure molding characteristics of alkyds, the high-pressure line may sometimes be cut out completely and only the low-pressure side of the system used. In general, not more than 4 sec. should elapse before charging the mold and applying full pressure in the case of granular and putty types, or 8 sec. in the case of fibrous glass-reinforced material.

In selecting a press to operate a specific mold for alkyds, the following rule should prove useful for average draws, the press should furnish about 1500 p.s.i. over the projected area of the cavity and lands for molding granular alkyds; about 800 p.s.i. for alkyd putty; and about 2000 p.s.i. for glass-reinforced alkyd.

Marked savings in labor, maintenance, floor space, power costs, and depreciation are possible through the use of presses specifically designed for use with alkyd materials. Detailed information and specifications are available directly from the manufacturers.

Design and construction

Alkyd parts are in successful production in positive, semi-positive, and flash molds. In general, the semi-positive and positive types are recommended to obtain uniformly dense parts with lowest shrinkage. Flash types, since they rely on the back pressure of the material for density, do not usually produce parts of maximum density due to the soft flow characteristics of alkyd materials. However, flash molds are frequently used with alkyd putty because of its low bulk factor. In any case, the use of polished, hardened, chrome-plated steel molds is recommended.

Positive and semi-positive molds should be designed for enough freedom to allow escape of material to prevent over-pressuring. Punch clearances on positive molds of the order of 0.004 to 0.005 in. are generally recommended for the granular and putty types. Slightly greater clearances are customarily used for glass-reinforced materials. Ex-

References were prepared by the editors.

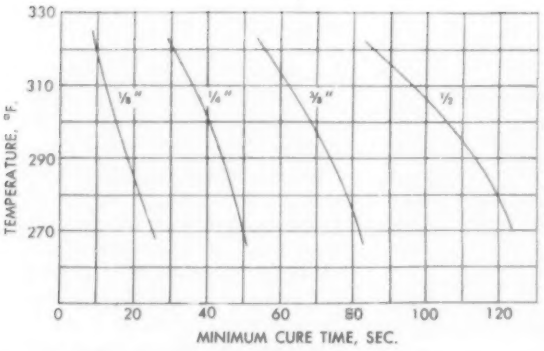

Fig. 1: Minimum cure time vs. temperature for various thicknesses of alkyd granular and putty materials

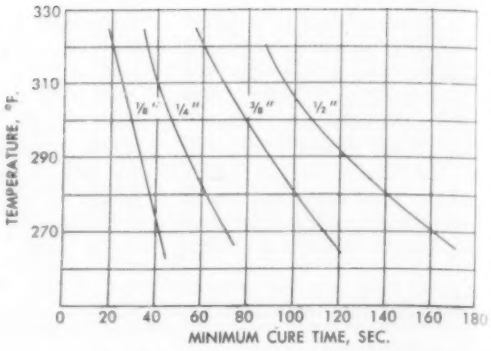

Fig. 2: Minimum cure time vs. temperature for various thicknesses of reinforced alkyd material

cessive clearances are to be avoided since they reduce the effective molding pressure on the material, and thereby cause a reduction in strength.

An allowance of 0.004 to 0.007 in./in. should be allowed for shrinkage from cold mold dimensions in the case of compression molded parts; transfer or plunger molding will result in somewhat higher shrinkages. This shrinkage is dependent upon mold design, shape of the piece, and in some cases on the pressure and temperature of the operation. It is highly reproducible on a given part. There is no measurable after-shrinkage on alkyd parts over an extended period since there are no residual volatiles or continuing chemical reactions involved after molding.

The use of transfer- or plunger-type molds is not generally recommended for molding putty or granular alkyd. In many such molds the plastic phase is too short to permit the material to complete its travel through the gates and runners before cure sets in. Precuring, even when it does not preclude complete filling of a mold cavity, can result in porosity, uneven density, and incomplete fusion. Such conditions obviously lead to loss of mechanical and electrical properties and to sharp deterioration in water resistance. In some cases, defects occurring in a transfer molded piece may be concealed to the eye but will cause trouble in testing or in service.

On the other hand, there are applications successfully in production on transfer molds in granular material. These transfer molds meet the following design requirements:

1) relatively small pieces to be molded; 2) cavities grouped very closely to the transfer pot; and 3) very wide open runners and liberal gating.

It has also been noted that parts molded in transfer cavities gated at two locations show poor mechanical strength, especially at the weld line. In general, parts molded by either straight transfer or plunger methods are lower in mechanical strength and lower in electrical insulating properties than similar parts molded by compression molding.

Reinforced alkyd may be transfer molded but the strength of such pieces is somewhat lower than that of compression molded pieces, the magnitude being almost entirely dependent on the size of the gates and the number of times the material changes direction before entering the cavity. Since these changes are dependent upon design, pieces will have to be tested individually in order to determine the suitability of the material for specific applications.

Multiple gates should normally be avoided because of the knitting effects between gates. An exception to this is the transfer molding of circular pieces for which knitting must occur to fill the cavity. In such cases, continuous circular gating is recommended. Better strengths are usually achieved by gating at the end of the piece rather than in the middle. When shrinkage tolerances are critical, it is recommended that both transfer ram and clamping pressures be sufficient to insure dense pieces.

Molds

To date, most alkyd molding has been done in molds utilizing conventional mold steels hardened by standard heat-treating methods. Other metals have been used for experimental and short-run molds. Some production molds have been chrome-plated while others are only highly polished, depending upon the preferences of the mold designer. The fact that the alkyds can be molded at low pressures has presented the possibility of using other than steel molds.

Alkyds, being mineral-filled materials, are somewhat more abrasive than general-purpose ureas or phenolics, and somewhat greater mold wear may be anticipated. Because of lower molding pressure and the greater plasticity of the alkyds, mold wear is not as great as it is with mineral-filled phenolics. The use of minimum pressures that permit satisfactory molding tends to reduce the effects of mold wear.

The usual precautions on design of pieces for thermoset molding should be followed. Particular attention should be paid to the use of flowing curves and generous radii rather than sharp knife edges. Sections should not be designed in any case for less than 1/16-in. thickness, and projections and ridges should be designed with generous allowances for material.

The fast-curing characteristics of alkyd molding compounds

should, of course, be taken into consideration when designing the number of cavities for a given production mold. The high production rate per cavity of these materials represents a definite savings in tooling cost.

Special considerations

Common characteristics of all glass-reinforced polyester molding compounds should be considered in designing parts. Some of these characteristics are: 1) a tendency to trap air in unvented draws; 2) a tendency toward internal porosity and internal cracking in heavy sections; 3) a tendency to crack or show poor strength when fiber alignment occurs due to flow obstruction; 4) a tendency to have relatively poor strength in thin sections; 5) a tendency to show porosity or poor end-fill on long, restricted flows; and 6) a tendency to show relatively poor dielectric strength in thin sections or in areas where fiber alignment may be normal to the conducting surfaces.

Although solutions to these difficulties may not always be possible through design alone, it may frequently be possible to avoid trouble by their careful consideration at the design stage.

Air entrapment in blind draws may frequently be overcome by venting at the top with a working pin. Sharp corners and square edges at the top of draws should be avoided in favor of radii whenever possible. It may also be possible to design the part so that the place where air may be trapped is isolated to a small area where it may be easily vented.

Although the internal porosity or internal cracking frequently encountered in sections heavier than ¼ in. may not interfere with the function of most parts, it may become a prime consideration if the section must be drilled or tapped or if electrical contacts carrying high voltage are to be molded in. In such cases, heavy sections should be avoided.

When the material flows around obstructions such as core pins, a certain amount of fiber alignment results. If the flow continues for a short distance beyond such points, the fibers tend to regain their random orientation and a good knit results. However, if the obstruction is near the end of the flow such as the extreme edge or top of the part, the fiber alignment may result in poor knitting or cracking. For this reason, location of core pins at extreme edges is to be avoided wherever possible. Otherwise, it may be necessary to use a vent or bleeder to obtain flow for a sufficient distance past the obstruction to accomplish good knitting.

Although sections thinner than 0.015 in. may be successfully molded, the strength characteristics are quite low due to fiber alignment and fiber breakage. In general, sections greater than 0.040 in. are to be recommended.

Because of the fast-curing characteristics of the material, it may be difficult to fill parts having long flows, especially if the flow is restricted by thin sections, core pins, inserts, etc. Although loading techniques may overcome this, it is recommended that long draws be accompanied by generous sections.

Fibrous glass-reinforced materials may show good dielectric strength by standard test methods in which electrode configuration and specimen shape and thickness are carefully specified. However, in actual applications in which voltage stresses may be concentrated at sharp corners and in which thinner sections may contain fiber-resin interfaces or other nonhomogeneous areas extending from surface to surface, glass-reinforced materials may show much lower dielectric strength.

Preheating and preforming

Although preheating of the granular or putty type is seldom necessary or desirable, reinforced alkyds are frequently preheated before weighing the mold charge to improve their handling characteristics. This is usually done in an air-circulating oven maintained at 130 to 140° F. for a period of 10 to 15 minutes.

It is also possible to use electronic preheating on reinforced alkyd. In this case the bulk factor is customarily reduced by mechanical or manual compression.

Because of the low bulk factor of the granular alkyds (approximately 2:1), it is seldom necessary to preform these materials. However, they will preform with ease on conventional equipment when necessary. The preforming pressure is much less than that required for phenolic or urea materials. To avoid excessively dense preforms, it is customary to reduce the pressure of the preforming machines to about one-fourth the amount used for preforming the conventional thermosetting materials.

As previously mentioned, the putty materials are usually preformed by extrusion. Extruders of both the screw type and the plunger type are in common use on these materials. An alternate method is to roll the putty into sheets of the desired thickness, from which ribbons or slugs may be cut and used as preforms.

Because of the relatively high bulk factor of the reinforced types, some preforming of the material is usually necessary. This is often done by simple hand compression after warming to 130 or 140° F. as previously mentioned. Mechanical preforming methods are sometimes used and machines have recently been developed to extrude material of this type into continuous ribbons or ropes, from which preforms may be cut.

In reinforced alkyds, the shape of the preforms will have a definite effect on the flow characteristics of the material within the mold. For this reason, some experimenting with preform shapes may be necessary. In general, the preform should approximate the shape of the mold but should be somewhat smaller to insure some flow of material. Multiple preforms are to be avoided because weak sections may be encountered at the interfaces or knit lines.

Molding techniques

The resin characteristics of alkyd molding compounds are such that the material goes through the very low viscosity phase momentarily when heat and pressure are applied. This low viscosity phase makes possible the complete filling of the mold at pressures much lower than required for other thermosets.

This phase is followed by a very

rapid, exothermic reaction which develops heat in excess of the mold temperature and which is responsible for the rapid cure of the material.

Since the reaction is a cross-linking polymerization, no products are given off in gaseous form; therefore, no breathing or holding is necessary.

Because the heat resistance of the material is relatively high, it is possible to leave parts in the mold at recommended molding temperatures for extended periods without risk of burning or overcure.

The most common molding difficulties experienced with alkyd molding techniques are precure of the material or use of excessively high molding pressures, or a combination of both.

Molding temperatures

The range of recommended molding temperatures extends from 270 to 330° F. In the majority of cases, mold temperatures in the range 300 to 320° F. will be most suitable. (See Figs. 1 and 2, p. 684.) In extreme cases, where long thin draws or slow presses are involved, temperatures as low as 250° F. have been used. However, the use of such low temperatures may tend to promote sticking, especially on mold surfaces which are not chrome-plated.

Under ordinary conditions, alkyd materials have good release characteristics and no lubrication is necessary to insure ejection from the mold. Hardened, chrome-plated steel surfaces are recommended. When sticking is encountered, it is usually due to too much pressure or insufficient temperature. When a mold has been running phenolic material, it is recommended that it be cleaned by running a few charges of urea or melamine before the alkyd is introduced, since the presence of phenolic resin, even in minute quantities, inhibits the cure of alkyd. Before returning a mold to the use of phenolic materials after running on alkyd, the same procedure should be followed.

In the transfer or plunger molding of reinforced alkyds, plunger pressures are largely dependent upon gate size. In general, a pressure which will bring the plunger home in about 7 sec. is recommended. However, successful cycles are in use with plunger times in the range from 3 to 12 seconds. Longer times are apt to cause precuring in the transfer pot or in the runners and gates.

Inserts

Because of the fact that alkyd materials have no after-shrinkage, inserts must be provided with generous knurls or undercuts to insure good gripping. Because of the soft-flow, low-pressure characteristics of alkyds, especially in putty form, many jobs involving delicate inserts have been run in these materials which could not be run successfully in any other thermosetting material.

Storage

An understanding of proper storage conditions for alkyd is perhaps more important than in the case of other plastics. The alkyd compounds are by nature more reactive than other thermosets and are, therefore, more sensitive to handling and storage conditions. Hence special care should be taken to follow the manufacturers' specific storage recommendations.

COMPRESSION MOLDING MELAMINE FORMALDEHYDE

BY H. J. WEST*

Properties of melamine formaldehyde molded parts vary according to the type of filler employed, but the moldings are generally highly resistant to water, mild acids, and alkalies and possess excellent dielectric strength and arc resistance. The alpha-cellulose-filled grades offer unlimited color, abrasion resistance, and durability. By the use of special fillers such as chopped cotton fabric, fibrous glass, or asbestos, specific properties may be emphasized for many important industrial applications.

Storage and handling

Storage under suitable conditions is of considerable importance in maintaining the as-shipped flow characteristics of melamine molding materials.

It is good practice to store at temperatures below 70° F. although the material should be allowed to warm up to at least 70° F. before charging the mold or preform machine. Attempting to preform too-cold material may cause unsatisfactory preform hardness.

Preforming

All standard commercial preforming machines should handle melamine granular molding material satisfactorily.

Preforming pressures range from 10,000 to 40,000 p.s.i., and depend on the size of the pill, the grade of material, the temperature of the material and speed of pressing. Pills must be hard enough to hold together during handling, but if too hard they may give poor molded parts. Pill-break marks may appear on articles molded from pills which are too hard.

The importance of temperature of the material in preforming is

* Plastics and Resins Div., American Cyanamid Co., 30 Rockefeller Plaza, New York 20, N.Y.
References were prepared by the editors.

illustrated in Fig. 1, right. The preforms will be too soft if the temperature of the material is too low. During the winter months the molding compound may be exposed during transit or in unheated storage to prolonged subroom temperatures. To bring the material to preforming temperature, it may be necessary to store it in a heated area for a day or more. Best results are obtained when the temperature of the material is 70 to 85° F.

When pills are made from powder or bulk material with hand dies, they are harder in comparison with pills made by automatic machines because of longer dwell under pressure. For this reason, large pills are sometimes hand pressed under reduced pressure. The longer dwell has an additional advantage in allowing more complete escape of entrapped air, giving a more durable pill.

In general, dies used for preforming melamine molding compounds should be of the highest quality steel hardened to 56 on the Rockwell C scale, polished to a high commercial finish, and hard chrome-plated. A taper of 0.002 in./in. on the diameter (0.001 in./in./side) is desirable to ease ejection and prolong the life of the dies. Figure 2, p. 688, shows satisfactory clearance ranges for punch and die using granular molding material.

Preheating

Melamine molding compounds can usually be preheated by any accepted method, but high-frequency preheating is most common and generally gives the best results. Preheating is strongly recommended to obtain the shortest molding cycles and to develop optimum properties and best appearance.

High-frequency preheating is most effective with preforms but granular material can be so heated if placed to a uniform depth in a shallow glass or polyethylene container. Variations in depth will result in nonuniform temperature in the charge.

Rag-filled materials can be shaped by hand and placed between the electrodes.

There is a normal variation in the thickness of preforms which cannot be avoided. If preforms of different thicknesses are placed side by side in an electronic preheater, they will not heat uniformly. One way to avoid this is to stack the pills during preheating. The ideal situation is to employ square or rectangular preforms which can be placed on edge, thereby eliminating the thickness variation. This is particularly advantageous where multiple pills are required.

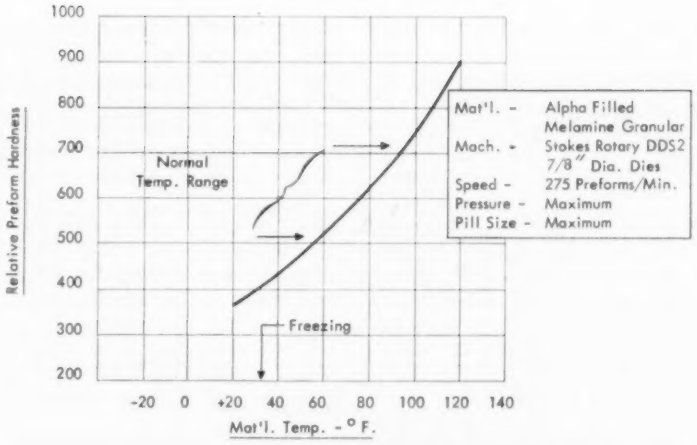

Fig. 1: Preform hardness vs. material temperature

The temperature range usually suggested for preheated melamine compounds is 220 to 250° F. The preform has usually reached a satisfactory temperature when it begins to swell and a small fracture appears at the periphery. Some large moldings are made with granular load preheated to 200° F. in a polyethylene or glass container.

Rotary-can preheating is usually less efficient than the high-frequency method but good results can be obtained if proper care is exercised. The containers must be carefully cleaned between heats to prevent overheated material from contaminating the subsequent charges.

Molding temperature and pressures

Melamine formaldehyde molding materials, like other thermosetting materials, soften and develop plastic flow under the heat and pressure of the molding operation. As the molding progresses, the heat induces a chemical condensation reaction and the material cures to a rigid, infusible molded part. The mold must be filled out with the material at maximum density before cure is allowed to develop. Time must also be allowed for moisture to escape before the material is fully cured.

Care must be exercised to insure that the material in the mold becomes uniformly heated throughout before closing the mold. Material in close contact with the walls of the mold may become too plastic before the rest of the charge is softened. Then, as the mold is closed, the soft material can be forced out before the remainder is properly densified. It is possible for the material adjacent to the wall to cure before full pressure is applied, resulting in a molding with a weak, poorly densified shell.

If moldings have adjacent sections of different thicknesses, too high a molding temperature may give both overcured thin sections and undercured heavy sections.

Because of the behavior of the material during molding, the temperature *vs.* cure curve for each grade of material must be considered in relation to the size and design of the part in determining the optimum molding conditions.

The rate of cure for any specific material is solely a function of temperature. Actual cure times may range from a fraction of a minute at 330 to 340° F. for molding buttons, to 3 to 5 min. for heavy moldings with mineral-

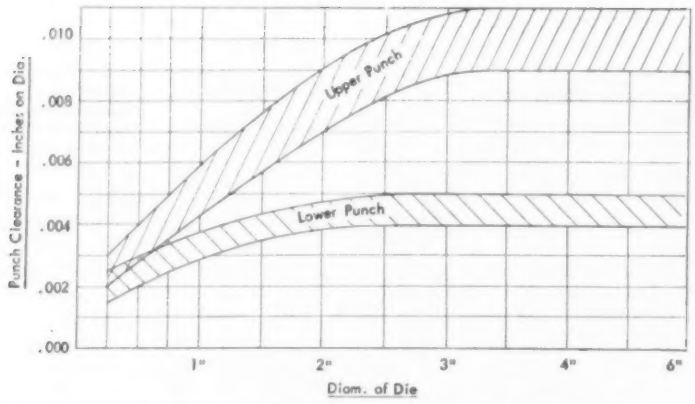

Fig. 2: Recommended punch and die clearances for granular melamine material

filled melamine molding material. Typical cure times for some different grades of commercial materials are shown in Table I, below.

Melamine resins are considerably less critical than urea resins in regard to temperature and duration of cure, resembling the phenolics more closely in moldability. It is relatively easy to impair the properties of ureas by overcure or "burning," whereas, because of much better heat resistance, melamine resins are much less sensitive to overcure.

Buttons and closures can be molded at high temperatures with fast cycles since the flow involved is of minor degree and the small cavity charge quickly reaches mold temperature. Large pieces requiring a high degree of flow in the mold and the transfer of heat through a mass of material require a longer cycle at lower temperature.

Pressure depends on several factors which include the size of the part, the depth of draw, whether or not the material is preheated, and the flow or plasticity of the material being molded. Typical compression molding pressures range from 1500 to 5000 p.s.i. Transfer molding operations require pressures from 4000 to 20,000 p.s.i.

Flow characteristics

The degree of flow or plasticity of the molding material under molding conditions is an extremely important factor. It has a bearing upon the kind of molding that can be made, the quality and properties of the molded p[art] and the type of mold that can [be] used. Flow must continue u[ntil] the mold is completely filled [out] under maximum pressure. Sm[all] parts of simple design are b[est] molded with stiff material. La[rge] objects require the use of easy-to-flow soft grades that will fill out the mold before the material sets. Fast-curing stiff grades can not be transfer molded since set may occur before the material is completely transferred.

The alpha-cellulose-filled melamine formaldehyde molding materials are generally supplied in varying grades of plasticity, designated as soft, medium, or hard. The softer grades are primarily designed for use in transfer molding, high-speed plunger molding, or compression molding of relatively large parts. The stiffest grades are used for molding buttons and other small parts.

Impact materials are normally available in a general-purpose plasticity.

The industrial grades of melamine formaldehyde molding materials—comprising wood-flour-filled material and mineral-filled material—are often used for molding parts for the electrical industries. Many industrial parts are of intricate design with metal inserts and are usually transfer molded.

TABLE I: Typical cure times at various temperatures for melamine molding materials[1]

Grade	*Temperature*	*Cure Time*	
	°F.	*⅛-in. disk*	*¼-in. disk*
Alpha cellulose	310	90 sec.	2 min. 15 sec.
filled[2]	320	60 sec.	3 min. 00 sec.
	340	50 sec.	1 min. 50 sec.
Cotton fabric	300	3 min. 30 sec.	4 min. 15 sec.
filled[2]	320	2 min. 45 sec.	3 min. 30 sec.
	340	2 min. 00 sec.	3 min. 00 sec.
Modified melamine—	310	2 min. 00 sec.	3 min. 00 sec.

filled[3]	330	1 min. 30 sec.	2 min. 30 sec.
Mineral filled[3]	310	1 min. 45 sec.	2 min. 30 sec.
	320	1 min. 30 sec.	2 min. 15 sec.
	330	1 min. 00 sec.	2 min. 00 sec.
Glass filled	300	1 min. 05 sec.	—

[1] Data are based on 4-in. disks of ⅛- and ¼-in. thickness compression molded of cold granular materials. [2] Cure to acid boil test. [3] Cure to appearance.

Decorative effects

Beautiful molded-in decorative effects can now be developed in alpha-filled melamine moldings by the use of resin-impregnated alpha-paper foils which have been printed with a decorative design. In using these foils, the compression molding operation is conducted in the usual manner and continued until the part is cured sufficiently to hold together well. The mold is then opened and the foil inserted with its printed side down. The mold is then slowly reclosed, full pressure applied, and held for final cure.

At the present time, most foils are flat sheets so that draw possibilities are limited.

Shrinkage

Shrinkage is an unavoidable phenomenon that occurs in varying degrees in the molding or

curing of all thermosetting materials. It occurs in two stages—during the actual molding operation and during the subsequent aging of the molded part in service. The two stages are known as mold shrinkage and after-shrinkage. The latter is mainly caused by continued loss of moisture or drying out of the part and continues until the moisture content is in equilibrium with the ambient relative humidity. Even then, dimensional changes may still take place through absorption of moisture under cool damp conditions followed by drying under warm, low-humidity conditions.

Typical shrinkage ranges for melamine molding materials are shown in Fig. 3, right. The values shown are given in mils/in. based on a 4 by ⅛-in. molded disk.

The degree of shrinkage varies with the following five factors:

1) *Type of material:* Shrinkage varies widely according to the grade of melamine formaldehyde molding material. The alpha-cellulose-filled unmodified melamine materials show the highest mold and after-shrinkage, whereas relatively low shrinkage is obtained with mineral-filled and impact grades. For example, a typical asbestos-filled material gives a combined mold and after-shrinkage of approximately 7 mils/in. and shows extremely good dimensional stability under environmental changes.

2) *Plasticity of materials:* Shrinkage generally decreases with stiffer flow since more of the chemical change has been effected in the material before molding.

3) *Preheating:* Preheating aids in removing volatiles before molding, thereby reducing shrinkage. This is particularly important when using soft material, for transfer molding, that would normally show high shrinkage. Preheating helps in holding after-shrinkage within a normal range.

4) *Method of molding:* Ample breathing of the mold permits escape of volatiles and may reduce after-shrinkage.

5) *Design of the molded piece:* Adverse effects caused by shrinkage on aging can be minimized by good design of the molded part. Nonuniformity of thickness in a molded piece tends to produce unbalanced shrinkage and consequent warpage. In the design of a piece in which adjacent thin and thick sections are necessary, generous fillets should be used in order that the change in dimension will not be abrupt. Thus, the best design is one in which wall thicknesses are uniform.

Material with high shrinkage on aging should not be used with large metallic inserts or when the part is to be used in an assembly which would prevent the release of strains set up in shrinkage.

Molding variables

A satisfactory molding cycle frequently depends partly upon the behavior of the mold itself; the procedure that will give the best results must be worked out by trial and error. The following observations should be helpful.

Gassiness: This is evident in the form of blisters or streaks of a lighter or darker shade than the main area. It is usually caused by the trapping within the mold, or in the molding, of water or volatiles. Sometimes it may be corrected by increasing the cure time, but usually, measures must be taken to release the volatiles before the part has completely cured. This may be done with a "breathe," which is accomplished by opening the mold ⅛ to ¼ in. while the charge is still plastic, holding it open for a second or two, and then completing the molding cycle.

Similar results may be obtained by partially closing the mold and holding for a few seconds before the final closing. This is called a mold preheat cycle.

Poor densification: This may show as voids within the piece or as a rough or pitted surface. It may be caused by any one or a

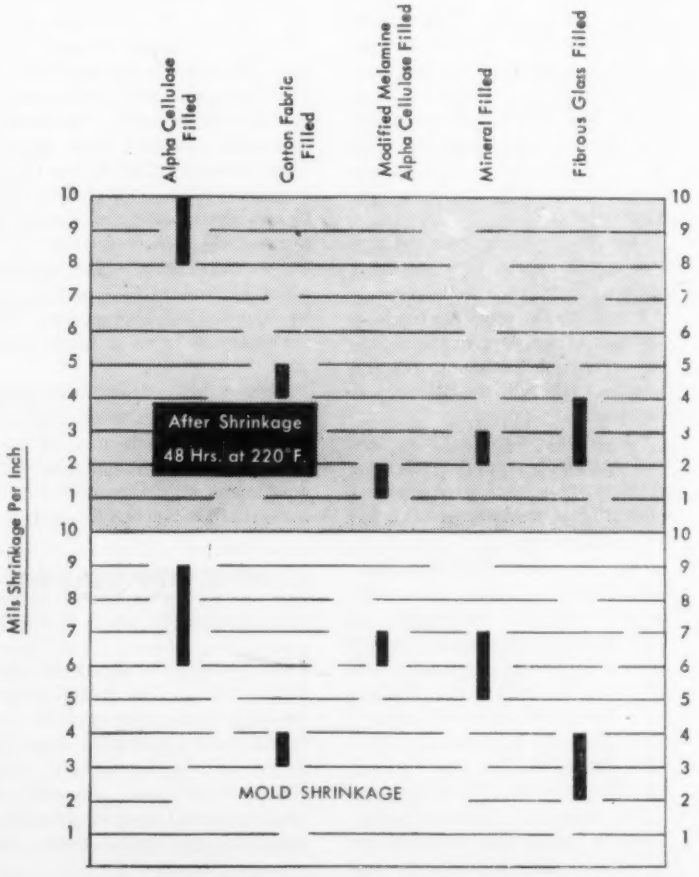

Fig. 3: Mold shrinkage and after-shrinkage of various melamine molding compositions (based on ⅛- by 4-in. compression molded disk)

combination of the following: too stiff a material (i.e., material sets before the flow is complete); too low molding pressure; undercharging the mold; and too fast or too slow mold closing. A study of the molding conditions should pinpoint the trouble.

Dead spots: These are generally white spots in the surface of the piece. They indicate the presence of prematurely cured material. This may result from the presence in the granules of material overcured during preheating, or from too slow a mold close at too high a mold temperature.

Flow and weld lines: Sometimes streaks or definite lines may appear where material has flowed and knitted together. There are several possible causes: 1) use of too stiff a grade of material; 2) excess cure in the transfer pot in transfer molding; 3) because material has flowed around a pin; and 4) because of turbulent flow. Breathe cycles may increase this problem.

Color segregation: This is usually evident as a mottled surface. A slower application of heat during preheating together with a higher final preheat temperature and then a lower temperature in the mold may help. A relatively slow mold-closing cycle is also often helpful.

Tear lines: Sometimes definite breaks will appear in the molded surface. They are usually a result of breathing the mold for too long a period or too late in the molding cycle. Adjustment of the breathe cycle will usually correct the trouble.

Pill break marks: These are surface defects caused by the use of excessively hard preforms resulting from preforming with too high a pressure.

Degree of cure: Parts that have been molded with the cure cycles recommended by the supplier of the molding material and which have satisfactory appearance will generally be well cured. Undercure may show up in the form of poor gloss or blisters. Overcure may cause surface crazing and can affect the strength of the part.

The cure of alpha-cellulose-filled or fabric-filled material can be evaluated by submitting a test piece to a 10-min. boil in sulfuric acid of 0.8% concentration. A properly cured part will show no chalking. Bad undercure will be evident as heavy chalking.

Glass fiber-filled

The foregoing considerations apply equally well to all grades of melamine resins, but additional precautions are required for the glass-filled grades. Because of outstanding electrical and mechanical properties, glass-filled materials are finding increasing industrial acceptance, but they are somewhat more critical to mold. Careful mold cycling is essential to obtain parts with optimum properties.

The glass-and-melamine resin compound has these unusual characteristics: 1) the resin does not impregnate glass fibers; 2) during molding only the resin softens and flows; and 3) the resin can flow away from the glass during molding, giving sections without reinforcement.

To minimize problems caused by this behavior, the following procedures are suggested: a) molding pressures should be 2500 to 3500 p.s.i., as excessive pressure contributes to resin segregation; b) mold temperatures should range between 280° F. for large parts and 320° F. for small parts; c) straight-close cycles should be avoided; d) high-frequency heating should be used whenever possible; e) time of cure should not be appreciably longer than that necessary to give a blister-free part.

Glass-filled materials may have to be hand preformed although the granular grade can be preformed on commercial automatic equipment with adequate care. It is most advantageous to use high-frequency preheating and to preheat as hot as possible. The mold should be "breathed" at least once to eliminate volatiles. These precautions should lead to the production of good molded parts. A good molding will show a uniform grayish color and show no spotting or staining when it is subjected to various types of ink or dye solution.

COMPRESSION MOLDING UREA FORMALDEHYDE

BY R. A. TILEY* and H. J. WEST*

Introduced to industry more than 20 years ago, urea formaldehyde molding compounds were the first thermosetting materials available in an unlimited range of color. Representing new concepts in molding speed, surface hardness, abrasion resistance, grease, oil, solvent, and heat resistance, urea formaldehyde molding compounds opened up broad new fields of application for molded plastics. They are, however, somewhat critical in behavior and must be handled by the molder with due respect to their fast thermosetting characteristics.

Under the influence of heat and

* American Cyanamid Co., 30 Rockefeller Plaza, New York 20, N. Y.

essure, molding compounds of ea formaldehyde pass through the characteristic cycle of flow, et, and cure. Chemical condensation is involved during the cure with the liberation of volatile materials, mainly water. To produce the highest-quality moldings, it is necessary for the molding cycle to be so devised as to allow for the effect of these chemical and physical changes.

In comparison with melamines or phenolics, ureas are somewhat more sensitive to heat during the early stages of cure; consequently, the precautions recommended for melamine (qv) apply with even more force to the molding of the ureas. Selection of material with proper flow and cure rate for the design and size of the molded part is of the greatest importance.

Ureas are generally available in plasticities ranging from very soft flow to medium-hard flow. The stiffer materials are used for small parts such as buttons and closures; the freer-flowing materials are suitable for larger articles such as radio cabinets and other housings.

Urea formaldehyde moldings are rated as boil-resistant but not acid-resistant. A suitable test for determining whether or not a part is adequately cured is to boil a test specimen in water for 30 minutes. A well-cured molding shows no chalking nor appreciable loss of gloss.

The following recommendations should be helpful in the handling and molding of urea molding compounds.

Molding conditions

Storage and handling: Ureas are usually supplied either in powder or granular form. It is good practice to store the containers in a dry area, preferably kept below 62° F. Under these conditions the ureas have excellent stability.

Preforming: Urea molding compound in granular form usually preforms well on any commercial automatic equipment. In general, ureas behave the same as alpha-filled melamines. (See "Compression Molding Melamine Formaldehyde," p. 686.)

Preheating: Although more sensitive to heat than the melamines, ureas, as granular material or preforms, can be successfully preheated by either radiant or high-frequency methods, provided certain precautions are taken. Local overheating must be avoided and the maximum temperature for preheated material is 185° F. (See "Compression Molding Melamine Formaldehyde," p. 686, for further suggestions on preheating techniques, which are applicable to the ureas also.)

A prewarming device is sometimes built into the press. One design incorporates an oil-jacketed section in the hopper discharge line. The oil is electrically heated by means of immersion heaters.

Molding temperature and pressures: Ureas are usually molded at temperatures ranging from 275 to 280° F. for large housings, to 350° F. for small parts such as buttons or closures. Molding pressures range from 2000 to 8000 p.s.i.

A "breathe" early in the molding cycle often helps to promote good densification, improve gloss, and shorten the cure cycle. A straight close, however, is often preferred in the molding of small parts. The following tabulation shows cure times for a typical urea molding compound using 4 in.-dia. disks, ⅛ in. and ¼ in. thick, compression molded from cold granular material.

	Cure time	
Temperature	*⅛-in. disk*	*¼-in. disk*
° F.	*sec.*	*sec.*
280	60	135
300	50	120
320	35	90

Buttons and closures can be molded at high temperatures with fast cycles since the flow involved is of minor degree and the small cavity charges quickly reach mold temperature. Large parts involving a high degree of flow in the mold and the transfer of heat through a mass of material are usually required to undergo a longer cycle at lower temperatures.

Shrinkage: Urea moldings show mold- and after-shrinkage ranges comparable to those obtained with alpha-filled melamines. The typical shrinkage ranges are:

Mold shrinkage 0.006–0.009 in./in.

Additional shrinkage, 48 hr. at 220° F. 0.006–0.012 in./in.

Degree of shrinkage depends to some extent on such factors as the plasticity of the material, whether or not the material has been prewarmed, the molding cycle, degree of cure, and the design of the molded piece. Problems caused by after shrinkage can be minimized by good design of the molded part.

Part and mold design

Compression molds can be positive, semi-positive or flash types, the semi-positive type being generally preferred. The most important features in design are those intended to offset stresses set up by differences in shrinkage, flow, and cure. Careful design of the molded part can minimize the effect of such differences. Good and poor practices to be followed are illustrated by Figs. 1 through 10, p. 692 and p. 693.

Openings should be placed so as to minimize flow differences as much as possible. Metal inserts must be thoroughly anchored in the die and should always be placed where there is an abundance of material in the part. Best practice provides a wall of at least three times the diameter of the insert. It is definitely inadvisable for the wall to be less than twice the diameter of the insert.

Wall dimensions should be as uniform as possible, particularly around openings. Differences in wall thickness can cause different degrees of cure and the resulting stresses can give warping or cracking in service.

Obstructions to flow must be avoided as much as possible and sharp-cornered right angles should be avoided since they give rise to eddying, resulting in flow marks and nonuniformity in strength.

Because of after-shrinkage and seasonal changes in dimensions, threads on closures should be made as deep as possible to provide satisfactory thread engagement in case swelling occurs.

Adequate clearance should be

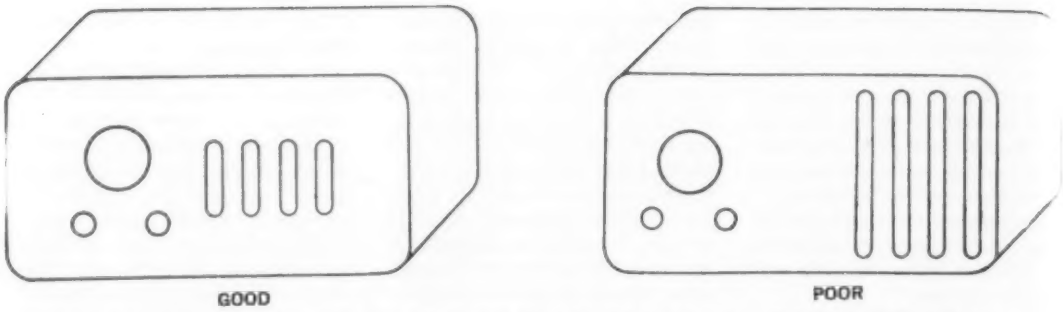

Fig. 1: Good design of molded urea pieces calls for openings to be well spaced and rounded (left), assuring even flow

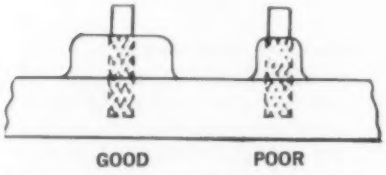

Fig. 2: Ample material should surround inserts: 3 times the diameter of inserts is preferred

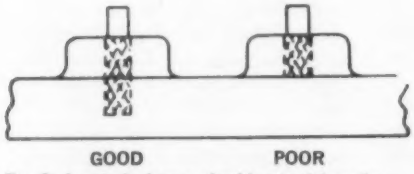

Fig. 3: Inserts in bosses should extend into the molded parts (left) for added strength

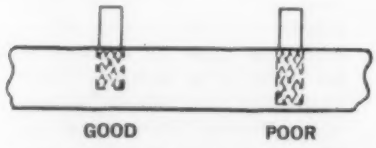

Fig. 4: Inserts extending almost through molded parts (right) often leave weld marks on surface of the part that is below the insert

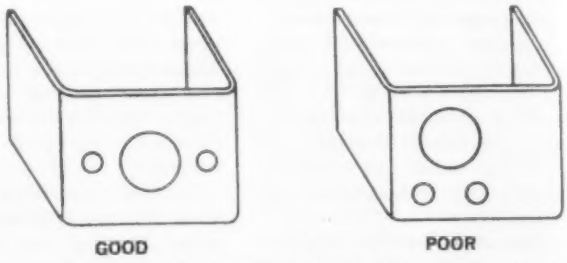

Fig. 5: For deep-draw parts, design at left is recommended for insuring that material flows evenly into vertical sections for formation of walls. Design at right makes for uneven flow

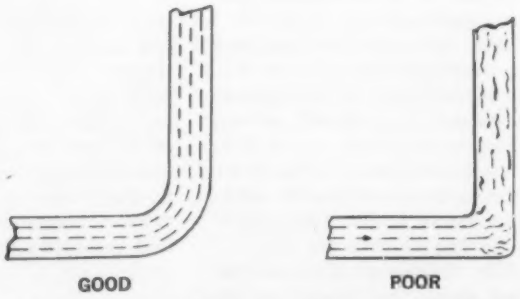

Fig. 6: Corner flow presents no problem if corner is rounded (left); if squared (right), material lodges in corner and impedes even flow during mold closing, causing flow marks and nonuniformity

provided at mounting holes to allow for movement caused by dimensional changes in the molding material.

Typical molded parts

Urea molding applications can be generally broken down into classifications such as: 1) buttons; 2) closures; 3) electric wiring devices; 4) housings; and 5) miscellaneous.

Miscellaneous applications cover a wide range of products, including knobs, dinnerware, and toilet seats, the most important differences being in the size of the part involved. In general, molding of these parts will be the same as for comparable parts in the other categories.

Buttons: Urea molding compounds are ideal for the molding of buttons. Using a stiff, fast-cure material, extremely fast molding cycles are possible. Fast, often semi-automatic flat-bed presses can be used with molds having up to 288 or more cavities.

Small flat preforms are generally used, which can be made from either granular or fine powder material. Cure temperatures are generally relatively high, ranging up to 350° F.

Fine powder material is often preferred for the following reasons: 1) lower initial material cost; 2) the possibility of coloring the material in the shop by ball-milling or micropulverizing with appropriate pigments, a procedure which eases inventory problems for the molder; and 3) greater ease of developing spe-

Fig. 7: Recommended practice when molding urea pieces is to have uniform or nearly uniform wall thicknesses (left). The bead in the center serves as support for the hole. Thin sections around openings (right) should be avoided since they may cure too rapidly and shrink unevenly, thereby resulting in a misshapen piece

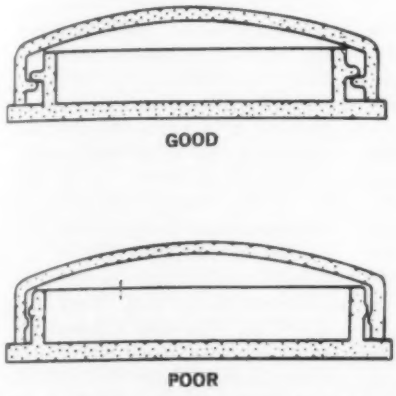

Fig. 8: Deep threads on closures provide satisfactory thread engagement without fear of normal shrinkage or swelling movements

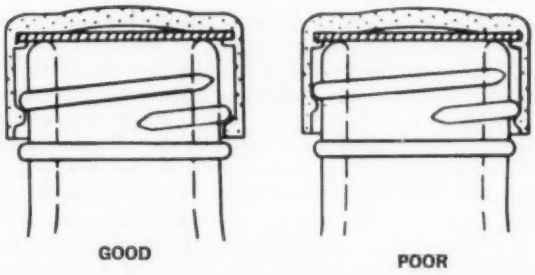

Fig. 9: Another recommended practice when molding urea is to allow clearance for shrinkage and use deeper threads (left) to insure thread engagement if swelling occurs

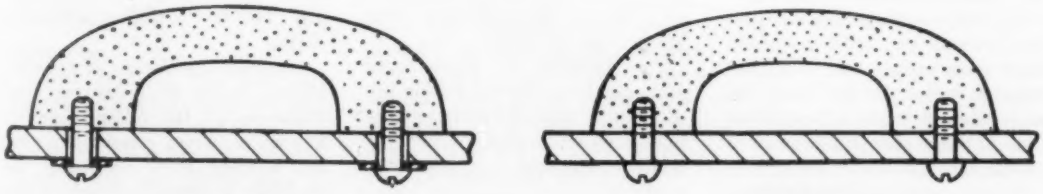

Fig. 10: Clearance at mounting holes allows for shrinkage movements (left); anchoring parts to metal may cause cracking

cial decorative effects, such as swirls, mottles, spatters, or similar attractive patterns.

The finishing of buttons is generally done by first tumbling for flash removal, then cleaning the holes with a special broaching machine sometimes designed by the molder, and, finally, tumbling for polish.

Closures: Because of their unlimited color possibilities, high gloss, and high degree of oil, grease, and solvent resistance, urea moldings are ideal for closures for cosmetic packages and similar articles. A properly-designed part has adequate torque strength for such applications.

Closures are often molded on fast automatic flat-bed presses, using either ball preforms or bulk loading. The force plugs in these presses are sometimes designed to unscrew the closures automatically. As the press opens, the plugs rotate by means of a rack and pinion and serrations in the cavities or out-of-round cavities prevent the caps from turning with the plugs. Rubber fingers complete the unthreading of the pieces. The closures drop into a catch pan and are blown or pushed out of the press; a loading board moves in from the other side to recharge the cavities.

Specially designed rotary presses are also used for closure molding. These are basically rotating tables with self-contained molding units (force, cavity, and ram) located on the periphery. Units can run to 30 or more.

As the table rotates past static

loading and unloading stations, the individual molds (1) open, (2) discharge a molded part, (3) receive a new charge of molding material volumetrically fed into the cavity, and (4) close. The cure is completed as the mold travels round to the first stage.

The part is usually unthreaded at the unloading station by means of a rubber wheel or belt, although in some cases the part is stripped.

This type of press is adaptable to molding small parts other than closures such as wiring devices and tube bases. Its advantages are relatively low tool costs, good molding speed, and ease of changing molds.

Some closure presses are operated manually and the caps are unscrewed individually with an electric or air-driven wrench.

Stiff fast-curing material is generally used for molding closures. Molding temperatures are usually relatively high, ranging from 320 to 350° F. Mold cycles should be kept as short as possible without undercuring the part. Undercure is often evident as blisters. Increasing the cycle a few seconds beyond the blister-point generally eliminates blisters and gives a satisfactory part.

Although a straight close cycle is preferred and most generally used, some presses are valved for breathe cycles. In any case, the press should have a controlled rate of close for uniformity of production.

Electric wiring devices: These include a wide assortment of shapes from switch triggers to multiple wall-plates. They are commonly molded on automatic and semi-automatic flat-bed presses as well as automatic rotaries. Because of irregular shape and design features such as internal bosses and rigs, relatively free-flowing material should be used. Materials classified as general-purpose with medium flow are generally considered to be satisfactory.

Typical molding temperatures fall within the range 300 to 325° F. Preheated material is often an advantage, particularly in molding larger wiring devices.

Housings: Large (200 to 500 tons) flat-bed presses manually operated are generally used for the molding of relatively large parts, such as radio cabinets and other housings. Because of the size of the part and the deep draws usually involved, material with a long flow period should be used. Grades classified as soft, or even very soft, may be required and some manufacturers offer a special grade of housing material.

Dependent upon the size of the housing, it may be necessary to keep the molding temperature as low as 280° F. with a 2½-min. cure for a material with very heavy cross-sections.

The molding of these large parts can be facilitated by the use of molding material preheated by high frequency, rotary can, or other suitable prewarming methods.

COMPRESSION MOLDING TETRAFLUOROETHYLENE

BY FRANK M. CHAPMAN*

Tetrafluoroethylene resins exhibit excellent thermal stability and an unusual retention of physical properties up to temperatures approaching the crystalline melting point. Tetrafluoroethylene resins are unique in that they do not melt and flow as do conventional thermoplastics. When heated above 621° F. (327° C.), the resin undergoes a transition from its normal crystalline state to an amorphous state. In the amorphous state, particles of tetrafluoroethylene resins fuse to give a structure of good strength. Based upon these characteristics, a number of processing techniques have been developed, which consist essentially of a cold-forming operation (preforming), followed by baking (sintering), and then cooling—as in powder metallurgy and molding ceramics.

* Sales Div., Polychemicals Dept., E. I. du Pont de Nemours & Co., Inc.
References were prepared by the editors.

Molding conditions

The tetrafluoroethylene resin general-purpose molding powder (Type I, A.S.T.M. Specification D1457-56T) has a particle size of about 600 microns and a bulk density of about 500 g./liter. Screening before use is good practice in order to insure disintegration of any particles that may be compacted during shipment. This can best be accomplished by employing a series of sieves, ranging in size from U. S. Sieve Number 3 up to a final U. S. Sieve Number 8 or a U. S. Sieve Number 10.

Tetrafluoroethylene resins are not hygroscopic. When shipped, the material contains less than 0.05% moisture. It is advisable to store powders of tetrafluoroethylene in a relatively dry atmosphere and at a temperature of from 70 to 90° F. (21 to 32° C.). This prevents condensation of atmospheric moisture onto the surface of the powder.

Resin which has become wet can be dried in trays filled to a depth of 1 in. and exposed for 1 hr. in a circulating-air oven at a temperature of 300° F. or 149° C.

Preforming: The preform is made by a simple compression of the powder at room temperature. Preforming and tabletting presses used in similar operations with other materials are generally satisfactory for preforming Teflon[1] tetrafluoroethylene resins.

Loading: The weight of powder placed in the mold controls the thickness of the finished piece. Therefore, when close tolerances are needed, it is necessary to maintain a constant weight load. Otherwise volumetric loading devices may be used.

Screening the resin just prior to loading improves the powder flow and reduces the tendency to "bridge" in a narrow die cavity. To produce a part which has a uniform density and shrinkage throughout, the powder must be loaded into the die cavity so as to give even distribution, and then leveled, all before compression. After one charge has been compressed, it is not feasible to load another charge onto this preform, because a fracture line will result between the first and second loadings. This fracture will not weld during the sintering

[1] Trademark, E. I. du Pont de Nemours and Co., Inc.

peration unless the piece is sintered under pressure as in the ase of ram extrusion.

Compression: It is important to avoid entrapment of air in the preform during the compression period. Air entrapment is more likely to occur in preforming large pieces. It can be avoided by reducing the speed of the ram toward the end of the stroke and by providing for a short dwell period when the die is about 90% closed. Too rapid application of pressure may cause cracks perpendicular to compression.

Preforming pressures of 1500 to 10,000 p.s.i. can be used, depending upon the shape, size, and cross-sectional area of the piece. The density of the finished molding increases with pressure up to 4000 p.s.i. but does not increase appreciably beyond that point. The use of excessive pressures may in some cases create fractures in preforms. Such fractures are usually 45° to the direction of compression and are believed to be shear planes caused by forcing one layer of powder past another. When the preform is to be 3 in. or more in length, it is advisable to apply pressure from both the top and bottom of the die to minimize pressure decay and obtain uniform density.

TABLE I: Coining: why and how

Reasons for coining	*Example*	*Temperature of coining mold*	*Coining pressure, p.s.i.*
1. To increase the final density of a molding	large sheets	cold	2000
2. To mold diaphragms or other thin shapes	diaphragm	500-600°F.	1000-2000
3. To produce complex shapes	molding with undercut	cold	5000-20,000
4. To improve tolerances	precision part	cold	2000-5000
5. To form glossy surfaces	sheets	cold	1000-2000
6. To prevent distortion	sheets	cold	500
7. To reduce fractures in large moldings, preform, sinter, and coin in the same mold	cylinders for skiving tape	720°F.	2000

Sintering

The preforms are generally heated in ovens at approximately 720° F. (382° C.) until the phase transition from the crystalline to the amorphous state is complete. The translucent appearance of a free baked molding in the amorphous state is a reliable index that this transition has occurred. Sintering times can be estimated roughly by allowing 1 hr. for each ¼ in. of the thickest portion of the minor dimension. However, when the polymer is sintered in a mold, longer times are required. These times can be estimated from the following relationship:

Sintering time (hr.) = 3.5 (R-R′)

where R is the inner radius of the mold and R′ is the radius of the mandrel.

Large moldings, (3 by 3 by 3 in.) should be heated slowly up to the sintering temperature. The rate at which they are heated through the transition temperature of 621° F. is critical, since the expansion of tetrafluoroethylene resins at this point is greater than at any other temperature. If the preform is heated too rapidly, nonuniform expansion will cause strains, which may produce cracks in the final molded piece.

Electrically-heated, forced-draft, hot-air ovens are generally utilized in the sintering operation. These ovens should have controls capable of maintaining temperature of sintering within from 700 to 730° F. (371 to 388° C.) Temperatures above 730° F. (388° C.) may have a deleterious effect on the physical properties of the molded part. The ovens, as well as the areas for cooling and coining, should be vented to the outdoors to remove any vapors that may have been evolved at these temperatures.

Cooling

Molded parts are cooled from the sintering temperature by free cooling, or coining either in the preform mold or a coining mold (Fig. 1, p. 696). The rate at which a part is cooled from above the crystalline melting point of 621° F. (327° C.) to temperatures of 575° F. (302° C.) influences both the final size and shape of the molding (3).[2] In general, rapid cooling of a molded piece gives less shrinkage, but lower density and greater distortion. Distortion and dimensional tolerances can be more accurately controlled by slow cooling, from the sintering temperature to about 575° F.

TABLE III: Mold dimensions for rods and tubes

Desired O.D. of piece, in.	*I.D. of mold*
1½ to 5	⅛ in. larger than O.D. of piece
5 to 10	¼ in. larger than O.D. of piece
10 to 15	½ in. larger than O.D. of piece

(302° C.), giving greater, but more uniform, shrinkage to the molding being treated.

Molding without coining

The following procedure is suggested for free cooling or molding without coining.

1) Sieve the resin directly into the die shell (U. S. Sieve Size 8 or 10), and distribute the powder uniformly throughout the mold cavity.

2) Insert the top-end plate and compress to about 4000 p.s.i. (Pressures between 1500 and 10,000 p.s.i. may be used, depending on properties desired and equipment limitations.)

3) Remove the piece from the mold and sinter 1 hr. at 720° F. (382° C.) for each ¼ in. of the greatest thickness.

4) If flat surfaces and close tolerances are important, cool from 720° F. (382° C.) to 575° F. (302° C.) at a rate not greater than 45° F./hr. (0.4° C./min.) and then remove from oven. If slight distortion is acceptable, the part may be removed from the oven without controlled cooling.

Pieces preformed at 4000 p.s.i. and cooled at 45° F./hr. (0.4° C./min.) will shrink about 4% in the dimension perpendicular to compression. A similar piece cooled in air would shrink about 0.7 per cent. Shrinkage at various conditions can be predicted (3).

Coining

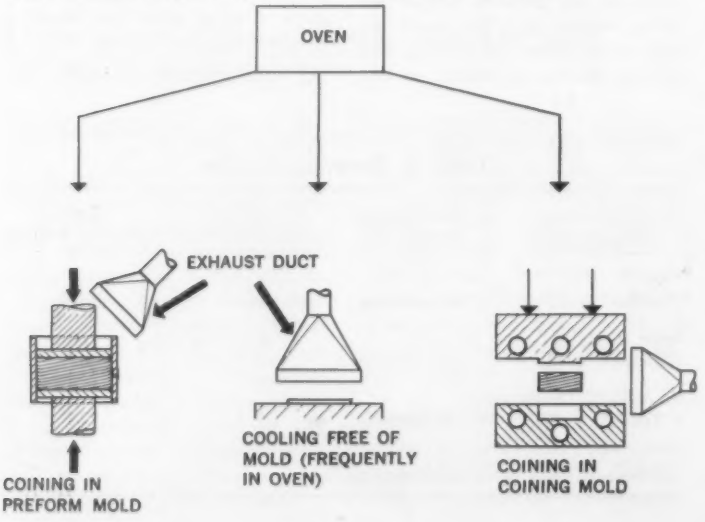
Coining is a technique of cooling under pressure in a mold. Two of the cooling methods illustrated in Fig. 1, below, are coining techniques. Pieces are coined for several different reasons as described in Table I, p. 695. However, the techniques are essentially the same. A piece above 621° F. (327° C.), (completely amorphous and translucent in appearance) is cooled under pressure in a mold. It may be removed as soon as it is cool enough to handle.

Pieces after coining will shrink appreciably during the first h[our] but will not reach complete eq[uil]ibrium for at least three da[ys]. It is difficult to predict t[he] shrinkage for any given pie[ce], but an approximate factor of [2.]5 to 2.5%, or 0.015 to 0.025 i[n./] linear in. can be used as a guid[e]. Parts preformed and coined at high pressures will have a lower shrinkage factor than parts processed at low pressures.

Mold design

Good practice in mold design for tetrafluoroethylene resins is similar to that used for thermosetting materials or powdered metals. For ordinary preforming at room temperature, the materials of construction are not critical. However, for accurate work, materials which can be hardened without distortion are recommended. The die shell and mandrel should be harder than the end plates to prevent galling. The molds used to fabricate the common shapes of Teflon tetrafluoroethylene resins are simple.

Preform molds: The cavities of preforming molds must be designed with sufficient volumetric capacity to compensate for the compression ratio and variation in bulk density of the resins. The compression ratios are shown in Table II, p. 695.



Clearance between the end plates and mold walls is not critical; a diametrical clearance of 0.004 to 0.005 in. is satisfactory. Too large clearances will cause excessive flash.

In preforming it is difficult to force powders of tetrafluoroethylene to flow. For molding complex shapes, this resistance to flow must be considered, and molds should be designed to minimize the requirement for flow, and to permit uniform compression on all sections of the preform. A correct design for a preform mold permits the proper distribution of powder before compression.

The shrinkage of a piece during molding must be considered in designing the preform mold. Having determined the desired process condition, the shrinkage can be predicted. (See discussion on shrinkage in the section on molding without coining.)

Molds for coining: Molds such

Fig. 1: Schematic diagram of procedures in compression molding Teflon

as coining molds which come in contact repeatedly with tetrafluoroethylene resins should be chromium-plated (about 0.003 in. thick) to prevent corrosion. If the molds are to be used for a limited number of pieces, the application of a silicone varnish (such as Dow-Corning Silicone Varnish DC-993) to the surfaces of the mold may prove more economical than chromium-plating.

Shapes that are flexible or tapered can be placed in the coining mold with no difficulty. For pieces with straight sides, a slight taper on the upper part of the coining mold will facilitate the entrance of the piece into the actual cavity. Sometimes the die blocks are cored for cooling or heating. The shrinkage of the part after coining must be considered in designing the coining mold. (This shrinkage is discussed in the section on coining.)

The size of the preform mold required for a coining procedure can be determined by the use of slugs machined from stock which was molded at the selected preform conditions. Following a trial-and-error procedure a slug is machined, which, in the amorphous state, would fit the coining mold. Then the preform die is designed so as to produce this slug.

The preforming die should be smaller than the coining die, since the preform will expand during baking. The linear expansion is about 7 to 9% in the direction perpendicular to the applied pressure, and up to 25% in the direction of pressure. Some shrinkage occurs during the transfer of the part from the oven to the coining mold.

When preforming, sintering, and coining are done in the same mold, the shrinkage depends on the diameter of the piece. Table III, p. 696, can be used as a guide for rods or tubes with wall thickness of ½ to 2½ inches.

In the case of tubes, the core is made to the required nominal I.D.

Effects of fabrication

Properties such as stiffness, flexibility, tensile strength, and dielectric strength are affected by the process variables. Void content and crystallinity are two basic factors that affect the final properties of a molding (2). Since the voids which exist in the preform may be carried over into the finished article, the preform pressure is important. The rate of cooling is a key factor since it determines the final crystallinity of the molding. Table IV, above, indicates the preform pressure, cooling rate, and the level of crystallinity necessary to obtain optimum values.

TABLE IV: Suggested conditions for optimum properties

Property	*Preform pressure*	*Desired crystallinity*	*Cooling rate*
Flexibility	Minor effect	Low	Rapid
Stiffness	Minor effect	High	Slow
Flex life	Maximum	Low	Rapid
Dielectric strength	Maximum	No effect	No effect
Resiliency	Minor effect	Low	Rapid
Impermeability	Maximum	High	Slow
Ultimate strength	Maximum	Low	Rapid
Yield strength	Maximum	High	Slow

When considering a combination of properties necessary for a specific end-use, it is important to note that the physical dimensions of a molded item may determine its final crystallinity by limiting the rate of cooling. Rapid cooling can be achieved for thin sections; however, in thicknesses greater than approximately ⅛ in. the cooling rate is limited by heat conductivity of the polymer.

Molding sheets

A uniform distribution of the resin in the preform mold is essential to the fabrication of sheets. This operation is best accomplished by first screening the polymer directly into the mold through a number 8 mesh screen, and then leveling the powder with a leveling bar. Slight irregularities in distribution can be smoothed out if a rubber pad is placed in the bottom of the mold. When the mold is initially closed, the ram should rest on the powder under its own weight for 3 min./each ¼ in. of the final thickness. The preform pressure of 2000 to 5000 p.s.i. should be applied slowly and maintained for 5 min./¼ in. of final thickness.

Sintering is accomplished in an oven maintained at 700 to 730° F. (371 to 388° C.). The data below can be used as a guide for the estimation of sintering times.

Caliper, in.	*Sintering time at 700–730° F., hrs.*
1/32 to ⅛	1
3/16 to ¼	1½
3/16 to ½	2
9/16 to ¾	3

The preformed sheets are fragile. A practical method for handling them is to sandwich the preform between two thin plates before sintering. This combination is readily handled and can be easily transferred from the sintering oven to a press for coining. Coining at 1000 p.s.i. minimizes warpage and improves the surface of the sheet.

Stress relieving

Residual stresses are present in moldings which have been coined or rapidly cooled. In service, particularly at elevated temperatures, the stresses in these parts will tend to be relieved, resulting in distortion and dimensional changes. These can be kept to a minimum by stress relieving before use. On the other hand molded pieces which have been free-cooled slowly are essentially stress relieved by reheating above the expected service temperature, but below the melting point and slowly cooled. As a rule, heat treating for 1 hr./in. of thickness is adequate when the molding is cooled slowly.

When extreme deformation during coining results in a high stress level, a molding will tend to revert to the original shape and dimensions of the preform at elevated temperatures. In such

cases, service will be limited by the temperature at which the part distorts.

Toxicology

Adequate ventilation is a recommended precaution against inhalation of small amounts of gaseous decomposition products encountered when processing tetrafluoroethylene resins at temperatures above 400° F. (204° C.). The use of proper ventilation is so effective that there are no known cases of ill effects where suitable precaution is taken.

COMPRESSION MOLDING PHENOLICS

BY A. J. GUZZETTI*

Commercial phenolic molding ing materials are available in a great variety, and the use of a specific type usually depends on the properties desired in the end product. These compounds incorporate either organic or inorganic fillers in ground or in macerated form. Some of the more commonly used fillers are wood flour, cotton flock, asbestos, mica, natural fibers, and even paper. More recently, fibrous glass, chopped glass cloth, and the new synthetic fibers have been introduced. The incorporated fillers sometimes cause a bulky molding compound. In such cases, the molding material is further processed to yield a product in pellet form, which results in easier handling during the molding process.

The terms "general-purpose," "impact-resistant," "heat-resistant," "chemical-resistant," or "special-purpose," are commonly employed to describe the various types of molding materials. This descriptive nomenclature usually refers to the outstanding properties that will be found in an end product fabricated from the specific material. Finished molded pieces are hard, rigid, and durable. With the diversity of phenolic molding material composition, the range of end products is almost unlimited, ranging from switch plates to large molded drawers.

To satisfy the thousands of phenolic molding applications, each with its own design, requires versatile and flexible fabricating techniques. It is also necessary to know how to handle the molding materials efficiently and economically, to have an understanding of good product design, and a thorough knowledge of the material and technique variables involved.

Preheating

Because of the many advantages that it offers, preheating of materials prior to molding is widely used. For example, it shortens the necessary cure time, and it reduces the magnitude of pressure required for the molding operation. Furthermore, any drying that is realized by preheating usually improves the electrical properties of the molding material and reduces shrinkage. Of the three general types of preheating —electronic, steam, or dry air— the electronic, or high-frequency, method is most frequently used.

Electronic preheating offers the advantage of very fast uniform heating throughout the mass of material. This directly implements savings in cure time, which tend to offset the initial cost of electronic preheating equipment. The economic advantages of electronic preheating and automatic molding have been combined, during the last couple of years, into a single automatic process. In such an operation, the powder or preformed material is electronically preheated, automatically transferred to the compression or plunger molding press, and automatically molded and ejected.

Where improved electrical properties are important, dry air preheating is of definite value because it effects greater drying of the material. However, it is the slowest preheating method and does little in the way of plasticating the material.

Steam or moist-air preheating makes possible control of moisture content in the material. On the other hand, it is much slower than high-frequency preheating and, generally, is in very limited use at the present time.

Molding methods

Molding methods generally fall into two broad classifications. In compression molding, the material, either loose or preformed, is charged into a heated mold. The mold is closed, generally under low pressure, until the two halves of the mold exert pressure on the material. Under this heat and pressure, the material becomes soft. As the mold continues to close, the softened material is forced into all parts of the cavity. Just before the mold is completely closed, high pressure is exerted and causes final and complete filling out of the mold. The high molding pressure is continued for the necessary period of time required for curing. Then, the mold is opened, and the molded part is removed.

The second type, plunger or transfer molding, involves the application of heat and pressure to the material outside the mold.

* Bakelite Co., Div. Union Carbide Corp., 30 E. 42 St., New York, N. Y.

References were prepared by the editors.

This secondary chamber is connected to the mold cavity by an opening called a sprue and channels from the sprue to the cavities, generally called runners. Again, pressure is continued for the time necessary for cure, after which the mold is opened and the parts removed. In this operation, a cull is sometimes left in the external chamber, and this must be removed before the next cycle is started.

Compression molding

Compression molding is best suited to producing parts of large area or deep draw. Furniture drawers, radios, and housings for instruments, meters, office and business machines, and similar box-like structures are usually compression molded. Compression molding is also commonly employed for large-scale production of simply designed pieces such as closures, tube bases, and buttons.

Compression molding is not normally recommended in the molding of intricately designed articles containing undercuts, side draws, small holes, and inserts. The flow of the material under high pressure may distort or break pins and dislodge inserts. Such parts should usually be made by transfer (or plunger) molding. However, the use of electronically preheated powder in compression molding appears to be overcoming most of these disadvantages and may broaden the application of compression molding.

Molding methods may also be classified according to the use of hand molds, and semi-automatic and fully automatic equipment.

When hand molds are used, the mold is assembled and charged on the bench, transferred to a press, and then disassembled and discharged on the bench. This method is used only with intricate molds and for extremely short runs. In semi-automatic molding, the mold is mounted in the press, with or without knockout pins, and is charged and discharged manually. Presses of this type may be manually controlled or of semi-automatic operation. The greatest volume of molding, particularly of large pieces, is performed on equipment of this nature. Several automatic machines may be run by one operator who provides a supply of material for each machine and periodically removes accumulated pieces which have been automatically molded and discharged. This method, employed for extremely long runs of small pieces such as closures and tube bases, is gaining increased recognition because of the labor savings permitted.

In automatic compression molding, the majority of presses feed essentially unpreheated powders or preforms to the mold. Thus, these machines (that do not provide preheating) have a particular sphere in which they are economically advantageous. For example, these machines are not recommended for the molding of pieces that: 1) contain inserts (unless these are fastened into the cooled piece as are tube base pins), since an operator is required to put the inserts in either the mold or hot piece; 2) require the use of shrink fixtures to prevent warpage on cooling; 3) have delicate core pins or extremely intricate detail; and 4) have thick sections which almost require H.F. preheating to achieve reasonable cure times. Pieces which are free from all these conditions can usually be molded economically on automatic presses from unpreheated powder.

In some cases, however, pieces subject to condition 4 (and sometimes also condition 3) can be economically molded on automatic compression equipment used in conjunction with automatic H.F. preheat provided: 1) spherical preforms can be used; or 2) powder can be preheated sufficiently and still be handled successfully.

The advantages to be realized in the use of compression molding are important from several standpoints. First of all, there is a wide variety of available semi-automatic and automatic compression molding machines. From a materials saving standpoint, there is less waste because there are no culls or runners to contend with. There is not much tendency for pieces to distort because of generally lesser filler orientation and more uniform flow pattern. Finally, it has been found that the use of compression molding provides better retention of mechanical properties, particularly with impact materials having coarse fibrous fillers.

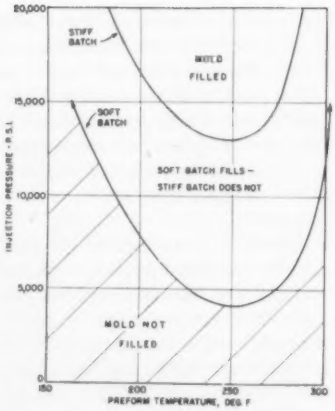

Fig. 1: Effects of pressure, preform temperature, and plasticity on fill-out in plunger mold. (Mold temp., 335° F.)

Plunger molding

Plunger molding has several advantages to offer over compression molding. The filling of intricate molds or molds with long core pins or inserts is accomplished better by plunger molding. In addition, shorter molding cycles are possible with plunger molding. There are two reasons for this:

1) The loading time is usually shorter since fewer and larger preforms are used. These can be preheated more rapidly and effectively in dielectric and steam preheating equipment. (Some dielectric preheaters are in use with loading boards for multiple-cavity compression molds, but they are more expensive.)

2) Shorter curing times are possible, particularly in thick sections. This is true because the material is heated as it is forced through the gate and the volatiles escape through vents and clearance spaces around movable pins.

Easier finishing is also possible with plunger molded articles since flash is quite thin or nonexistent. Gates can usually be made sufficiently thin and so located that their removal is easy and inexpensive.

There are several disadvan-

tages of plunger molding when compared with compression molding. The material left in the pot and runners is completely reacted and must be discarded. This loss is unavoidable and can represent a sizable percentage of weight of the pieces which are thus being molded.

Loss of mechanical strength with improved-impact materials containing fibrous fillers has been observed in plunger molding. Furthermore, plunger molding is less adaptable to the fabrication of large pieces, and the development of automatic plunger molding machines has been slower than that of automatic compression molding.

Plunger molds

Experience with different types of presses and mold designs indicates the following to be good practice: Individual hardened steel cavities should be mounted in the chase plate, which should be cored for steam heating. Runners and gates should also be hardened. The cavity and chase plate land areas should be ground and polished to insure maximum surface contact when the mold is closed. This prevents flashing of the material from cavities and runners.

The mold should be adequately supported directly under the pressure chamber to prevent distortion or sagging. If this precaution is not taken, mold distortion will result and cause flashing and nonuniform filling of the cavities.

The gate to the cavity should be located on an easily accessible surface, so its removal may be accomplished by a simple finishing operation. Care should be taken not to gate the cavity directly opposite a mold pin or other protrusion in the mold. Gating at such a point will cause the stream of material entering the cavity to change its direction of flow and divide into two or more streams, tending to cause weld marks and knit lines and to decrease the physical strength of the molded piece. Gate size may range from pinpoint to 0.500 in. wide and 0.125 in. deep. In the molding of comparatively small pieces using general-purpose phenolic material, a gate 0.100 in. wide and 0.015 in. deep will usually prove satisfactory.

Proper venting of the mold is essential to permit the escape of air trapped in the mold prior to injection of the material. Vents should be located on the same half of the mold as the runners, at the point which fills out last. This is generally furthest from the gate, thus facilitating the sweeping out of air and preventing gas entrapment. Vents 0.002 in. deep and 1/16 to 1/8 in. wide generally are adequate.

Molds used in plunger molding normally are multiple cavities. However, the number of cavities possible in a plunger mold is less than that possible with a compression mold. As a rule, plunger molding is performed on semiautomatic equipment. Fully automatic machines are being used, particularly in the molding of small pieces, and the development of this process on an automatic basis is continuing.

Mold design

In designing a piece to be molded, adequate draft must be provided to permit easy removal of the piece from the mold. Wherever possible, corners should be rounded to avoid stress concentrations. Sections should be of uniform dimensions; nonuniform sections promote gas entrapment, warpage, and internal stresses. Where inserts are necessary, special provisions must be made for them. In calculating mold dimensions, care must be taken to make proper allowance for shrinkage and cut-off. Small undercuts may be used in one of the mold halves to insure retention of the piece on a particular half of the mold. Proper design of the mold is also important from the general standpoint of molding materials. Specifically, a sufficient number of steam channels or electric heating elements (depending on the method used) must be carefully located throughout the mold to insure uniformity of temperature from point to point.

Materials and methods used in the construction of molds are of primary importance in determining both the quality and cost of the finished piece. Molds machined from tool steel, although expensive, are superior to other types. To produce molds of this type, tool steel is machined to the proper shape, hardened, and then ground to final dimensions. Hobbing steel may be used to produce molds where a large number of cavities are to be made. In this process, the individual cavities are formed by pressing a hardened steel hob of the desired shape into low-carbon, or hobbing steel, which is then case-hardened to produce the finished mold cavity. Chrome-plating of metal molds provides an excellent surface, improves release properties, and increases resistance to mold staining.

Molding operation

The molding of phenolic materials may be performed under varying conditions of temperature, pressure, and cure time. The temperature of the charge may vary from room temperature, when preheating is not used, to 300° F., the maximum preheating temperature normally employed. Mold temperatures vary from 290 to 400° F. but are generally in the range of 315 to 365° F. In compression molding, the average pressure is approximately 3000 p.s.i. A pressure of this magnitude is usually sufficient to mold the majority of parts, using general-purpose molding materials. Pressures used in plunger molding processes average about 8000 p.s.i. Molding cycle time may vary from a few seconds to several minutes and is greatly affected by the nature of the piece, material, and technique. All of these molding conditions are affected to a greater or lesser degree by the design of a specific mold and by the types of material to be used. Thus, in selecting conditions for a particular molding operation, the size, techniques, and intricacies of the molded piece must be considered along with such interacting variables as type of material and its plasticity.

The two major considerations in fabricating a piece by compression or plunger molding are the production of the piece in keeping with specifications and the most economical production of this specified piece. To attain these ob-

jectives, a thorough understanding of the abovementioned molding, piece design, and material variables is necessary. And once optimum conditions have been agreed upon for a specific molding operation, it is imperative that these conditions be carefully maintained and controlled throughout the entire job. Pieces thus produced will exhibit uniformity of specified properties and will have been economically produced under the closely controlled optimum conditions.

Material plasticity

The plastic behavior of a molding material as it is molded is determined by two things: 1) the flow properties of the material; and 2) the molding conditions. The rheological (flow) properties of the material are numerous and complex, and their complete definition would require determination not only of several rheological properties as a function of temperature, but also the time rate of change of these properties. For practical purposes, material plasticity is defined in terms of specific molding tests which roughly simulate conditions of use in the field. These ratings do not, and cannot, completely define material plasticity. They do serve: 1) to predict relative performance of different batches of the same material under all conditions of use; and 2) as a first approximation of relative performance under various molding conditions.

It is evident that a low degree of plasticity or a high degree of plasticity or a high degree of reactivity may result in failure to fill the mold properly. In this case, the rate of flow and reactivity of a material—under the particular conditions of temperature, pressure, and time cycle of operations employed—are such that the material becomes too stiff to flow further. Excessively soft material may also give rise to a variety of less evident molding difficulties such as: 1) gas entrapment; 2) poor release; 3) slower cure; 4) loss of any mottle pattern; 5) flashing of transfer molds; and 6) greater shrinkage. Appearance may be adversely affected by either excessively high or low plasticity.

Molding plasticity of a single batch of material can be altered by such conditions as preheat temperature and molding cycle. The principal molding conditions which affect material plasticity

TABLE I: Variables affecting mold shrinkage

Molding variables		*Mechanism*			
		Thermal contraction		*Elastic recovery*	*Plastic deformation*
Principal variable	*Effect on shrinkage of increasing variable*	*Piece temp.*	*Coeff. th. ex.*	*Pressure on piece*	*Mechanical distortion*

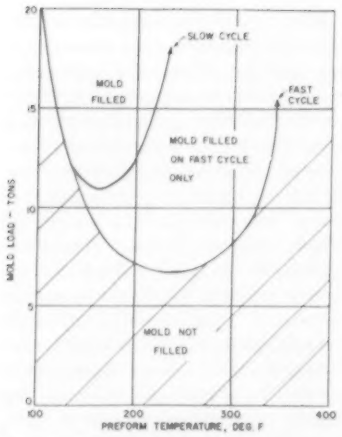

Fig. 2: Effect of time cycle of operations on range of mold fill-out of compression mold. (Mold temp., 335° F., H.F. preheat)

are: 1) pressure on the material; 2) preheat temperature; 3) time cycle; 4) mold design, and 5) mold temperature. The combined effects of some of these variables are illustrated by Figs. 1, p. 699, and 2, above.

Figure 1 shows the ranges of preform temperature and injection pressure over which a particular plunger mold could be filled with material of two different plasticity grades. It is seen that as preform temperature increases, the pressure required to fill decreases to a minimum and increases again. At the minimum, the softening effect of increasing preheat is offset by the increasing rate of the chemical reactions which result in hardening. Though the two batches differ widely in plasticity (as evidenced by the difference in the minimum values of the two curves), the pressure required to fill the mold with the softer batch varies over an even greater range as the preform temperature changes. This is shown by the fact that, at 175° F. preform temperature, the softer batch requires more pressure (15,000 p.s.i.) to fill the mold than did the stiff batch at 250° F. preform temperature (13,000 p.s.i.).

The effect of the length of the molding cycle on plasticity, as judged by mold fill-out, is illustrated in Fig. 2. These data were obtained in a compression mold using a single sample of material. The fast cycle involved transferring the preheated preform to the mold, running it for 10 sec., and then closing the mold rapidly under pressure. In the slow cycle, transfer and run-up time were increased to 30 sec. and the closing under pressure was slowed by restricting the pump output.

It is evident that the slower cycle greatly increases pressure requirements and decreases the allowable range of preform temperatures. This is due to the greater amount of reaction occurring in the preheated material during the longer time required for transfer and flow in the slower cycle. The data show that very close control of time is required if the advantage of high-temperature preheat is to be fully utilized.

Variations in mold design, such as gate size (in transfer molds), wall thickness, and depth of draw, can exert similar profound influences on pressure and preheat requirements. Gate wear can alter pressure demands appreciably. Preform temperature is rarely controlled to a specific value in molding operations. Variations in preform density (resulting from changes in preforming pressure) and electrode spacing may result in significant differences in temperature and, consequently, in plasticity.

Most molding compounds are offered in a rather wide range of plasticities to meet nearly any set of conditions encountered in various molding operations.

Molded piece dimensions

Molded plastics parts, with few exceptions, are smaller than the molds from which they are produced. This difference in dimensions, or molding shrinkage, though it may be only a few tenths of 1%, is of considerable importance when dimensional tolerances are exacting. Components of assemblies, large pieces which are to be spray painted through a mask, and long molded furniture drawers are examples of moldings requiring very close control of certain dimensions, sometimes as close as 0.001 in./in. of length.

Molding shrinkage is defined as the difference per unit length, in any linear dimension, of a mold and a molded piece when both are at room temperature. The shrinkage is equal to the dimensions of the mold minus the dimension of the piece divided by the dimension of the mold. A differentiation should be made here between molding shrinkage and so-called "after shrinkage." The latter usually results from exposure of the molded piece to certain environmental conditions.

The mechanisms by which molding shrinkage occurs are: 1) thermal contraction, which is a function of the ejection temperature of the molded piece and coefficient of thermal expansion; 2) elastic recovery (expansion that tends to reduce shrinkage): this depends directly on the compressibility of the material and the actual pressure exerted on it; and 3) plastic deformation, which is caused by mechanical distortion.

The variables affecting these shrinkage mechanisms can be divided into three categories: 1) molding; 2) mold and piece design; and 3) material. Table 1[1], p. 701, summarizes these three types of variables.

Molding speed

In recent years, the rapid growth of thermoplastics has brought these materials into competition with phenolics in many fields where economy of molding is the principal consideration. Since the higher molding costs of phenolic materials are largely a result of longer molding cycles, interest has been concentrated on reducing phenolic molding cycles to a point nearer those of the thermoplastics.

The minimum requirements for commercially cured phenolic pieces are usually: 1) sufficiently rigid: [so as not to A) strip prematurely over undercuts designed to hold it in one or the other mold half, or B) distort unduly during ejection and subsequent handling before it is cold]; and 2) free from undercure blisters caused by entrapped air, water vapor, or volatile matter formed during cure.

As with plasticity and shrinkage, molding speed can be varied

[1] "Shrinkage of thermosets," by A. J. Guzzetti, MODERN PLASTICS *34*, 111 Feb., 1957.

greatly by altering molding conditions. The most important variables affecting molding speed are charge temperature and mold temperature. The charge temperature, or temperature of material entering the mold, is the biggest single variable for pieces of any size. It is especially important in the case of thicker pieces because the poor thermal conductivity of phenolic materials retards heat transfer from the mold to the center of the material. Conversely, mold temperature is most important in thin sections where low charge temperatures are used.

Time, temperature, and pressure are the variables which control the cure of a thermosetting material. The effect of time is always in the same direction. Longer cure time, unless decomposition or rearrangement occurs, results in greater rigidity up to the point at which essentially complete reaction is attained.

Variations in temperature affect rigidity by two mechanisms which are opposite in their effect:

1) Higher temperature results in faster reaction and, thus, in a more highly cross-linked, rigid, molecular structure at any fixed cure time.

2) For any given molecular structure, higher temperature results in lesser rigidity by virtue of reduction in the retardation times.

Mechanism (1) predominates at low degrees of cure (short cure times and lower temperatures), and mechanism (2) stands out at higher degrees of cure. These effects are shown in Fig. 3, right. At the shortest cure time, pieces cured at 365° F. were almost three times as rigid as those cured at 305° F. due to faster chemical reaction at the higher temperature. As cure time was lengthened, the effect of temperature on retardation time became more of a factor. At the longest cure time, pieces cured at 365° F. were only about half as rigid as those cured at 305° F. Thus, if cure time is not also taken into consideration, the resultant cross-over can give rise to conflicting reports on the effect of temperature.

An increase in molding pressures, at constant temperature, generally appears to retard the curing reaction with a subsequent reduction in rigidity. Experimentation has indicated this to be true for one-step and two-step materials, for woodflour-filled and mineral-filled materials. A rise from 1000 to 6000 p.s.i. of pressure has been found to cause reductions in apparent modulus that vary from within experimental error to 20 to 30 percent. This does not mean that reducing molding pressure will always result in greater rigidity or faster cure. There are other controlling factors, including the heat generated by mechanical work done in flowing the material, which are likely to predominate. But it does suggest that, with flat pieces where very little flow is involved (for example, switch plates), cure may sometimes be accelerated by use of lower pressure.

The minimum blister-free time decreases sharply as preform temperature is increased. In the case of pieces having a very thick section, the reduction effected is as much as 75 percent.

The maximum preform temperature at which pieces may be molded is limited by material properties and by the formation of appearance defects (e.g., shallow surface blisters, etc.), but the chief limitation on the maximum preform temperature is the time cycle of operations. This is illustrated by Fig. 2, p. 702, where it is shown that increasing the time required to transfer the preforms to the mold and slowing down the press resulted in a drastic reduction in the maximum temperature to which the material could be preheated and the mold still filled.

Automatic molding

More and more development work is being conducted in the field of automatic molding processes which combine fast high-temperature preheating, rapid material transfer, and faster-closing presses.

Automatic preheating of preforms, coupled with automatic compression molding, although patented years ago, has only recently been commercially exploited. This process, however, permits productivity increases of

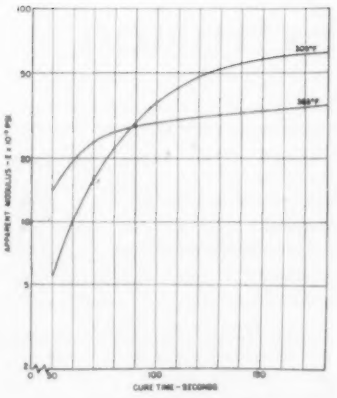

Fig. 3: Effect of cure time on rigidity of a general-purpose phenolic at two temperatures

50 to 100 percent over that obtained with cold powder. Considerable success has also been achieved in automatic powder preheating.

In all automatic processes, means must be provided to afford close control of molding conditions. This is necessary to obtain the full advantages of higher material and mold temperatures without danger of thermal deterioration. Close control of molding conditions will also permit material manufacturers to formulate compounds having faster molding speeds but greater susceptibility to thermal abuse.

Extrusion is any process by which a material that does not deform rapidly under light loads is forced under relatively high pressures to flow through a restricted opening. The operation imparts a new shape to the extruded material or, as it is also known, the "extrudate." Toothpaste forced out from its tube, hamburger from a meat "grinder," or cake decorations from a syringe are everyday examples of extrusion. (In all three instances, there is a shaping function as well as a transport function.)

In plastics processing only screw extrusion and ram extrusion are used, and ram extrusion has important application only to the processing of TFE resin (Teflon). The discussion of ram extrusion, therefore, will be found in the article on extrusion of TFE resin, p. 725. This introduction will be concerned only with screw extrusion.

Extrusion process

A screw extruder (see Fig. 1, p. 705) has five basic parts: the screw, the barrel that contains it and provides drag on the material, a drive to turn the screw, a feed port, and the die, or shaping orifice, at the delivery end. Since most plastics are too rigid to extrude at room temperature, they must be heated considerably before they pass through the die. Since at least part of this heat is supplied by direct transfer through the barrel, heating equipment is furnished with the extruder.

The screw can be thought of as having three zones—feeding, plasticating, and metering zones—though the transition from one to another may sometimes be indistinct. Each has its function, as discussed below.

Feeding

The plastic to be extruded enters the feed hopper in the form of small pellets (about ⅛ in. on a side) known as molding powder. Very soft stocks, such as plasticized vinyl, and various rubbers may be fed in strip form. The powder falls into the screw and attempts to rotate with it, but is held back by the drag of the stationary barrel. Because it is dragged back (the term "drag flow" applies to this action and is discussed on p. 705), the spiraling screw flight advances it axially. If the drag of the barrel could make itself felt fully throughout the entire mass, the plastic would advance in the form of a plug, much as a nut that is held advances when the bolt is turned. On the other hand, if there were no friction at the barrel surface, we have the opposite action: no matter how much the screw turns, there is no advance (analogous to a nut that is *not* held).

The feeding action in plastics extruders occasionally approaches one of these extremes, but more nearly always lies somewhere between. The rate of advance thus depends on the friction between barrel and plastic and between the screw and the plastic, as well as on the screw geometry. Back pressure also affects advance, as would be expected. Equations describing solids movement in extruders were developed by Darnell and Mol (11)[1], who assumed that the solid mass is not sheared, i.e., behaves as a plug. Calculated results agree well with experimental outputs measured in 2-in.-dia. screws; divergences are due mostly to the difficulties of determining the coefficients of friction to be used.

Some of the qualitative results of this theory were reached earlier by H. Decker (35), whose equations, however, were quantitatively inadequate. They are: 1) minimize friction between the plastic and the screw, by minimizing the contact area on the screw, by polish, or by chrome plating; 2) develop as high a coefficient of friction as possible between the plastic and the barrel, by roughening the barrel surface or even cutting grooves in it; 3) choose the lead and profile of the screw to get the greatest axial components of motion and pressure; and 4) have a high bulk density in the feed. These conclusions, borne out by the later quantitative work (11), imply that multiple flights are detrimental to good feeding, and that dense, compact pellets rather than fluffy feeds should be used.

The form of the particles fed into the extruder is also important, particularly in the smaller machines where the particle size is almost as large as the thread depth. Kennaway (20) tested various polyethylene feeds—rough cut particles, cubes, cold-cut spaghetti (cylinders), and hot-cut spaghetti (spheroids)—and found that spheroids gave higher, more regular output.

Plasticating

In the next stage of the extruder, the pellets are crushed together and eventually fused into a molten mass that wets the barrel and screw surfaces. During this transition, the density of the material, in bulk, increases sharply, sometimes as much as six-fold. With molding powders a two- to four-fold change is common. This change is allowed for by a corresponding change in the volume of the screw flight, and the ratio of the screw volume at

[1] Numbers in parentheses link to References listed on p. 708.

the feed section to that in the last turn before the die is called the *compression ratio* of the screw.

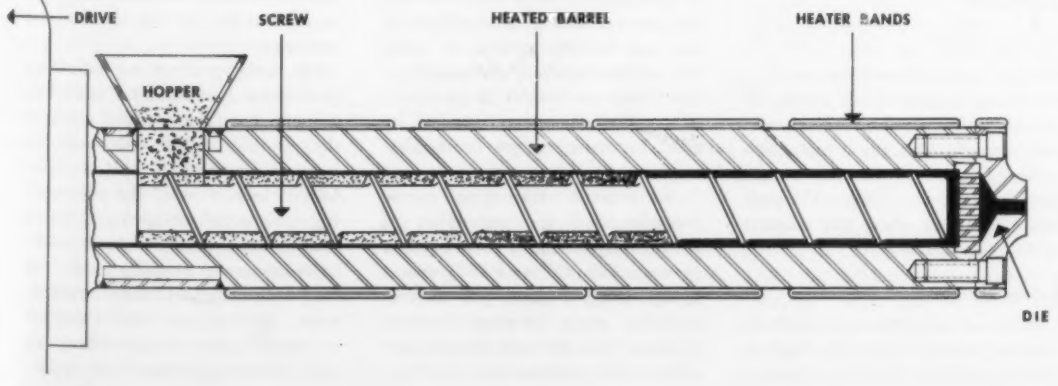
Since we still know very little about the details of what happens to the feed particles during this plasticating or compression stage, there is still tremendous divergence among screw designers and extruders as to how this zone should be designed. There are screws in which the change in volume occurs almost as suddenly as a stair step—in half a turn of the screw. In others it begins with the second turn and is completed in the next to last, by gradually decreasing the lead or the thread depth of the screw, or both. In some, thread depth is decreased conically, in others helically. Information is lacking that would permit a sound decision as to just what method to use. What is known about the subject, however, is as follows: 1) compression should not begin until the feed has been brought up to a temperature in the neighborhood of its heat-distortion temperature or else bridging and stoppage of flow may occur; 2) if the feed section preceding compression is too short, slight fluctuations in back pressure can cause wide variations in feed rate; 3) a comparative study of polyethylene extrusion in two screws having the same compression ratio showed the decreasing-thread-depth screw gave higher, steadier rates than the decreasing-lead screw (27). Also, for other reasons, given below, the decreasing-thread-depth method is much preferred to the decreasing-lead method.

The metering zone

Most screws made today for extruding plastics have a definite metering zone. This is the last threaded section of the screw, relatively shallow in thread depth, and with constant lead and depth throughout. As its name implies, its function is to regulate the rate of extrusion through the die. If the extrudate dimensions are to be kept within narrow limits, variations in extrusion rate must be reduced to the attainable minimum. Since the extrudate is usually handled by take-off equipment running at constant lineal speed, any variation in extrusion rate causes an equal variation in the cross-section of the product.

The operation of melt screws, and metering screws especially, is well understood. It happens that in melt screws, the non-Newtonian flow behavior of plastics has little influence on screw performance, so Newtonian flow theory applies rather well. The problem of output and pressure development in screw pumps was first solved by Rowell and Finlayson (36) and subsequently tackled with varying degrees of success by several other parties, apparently working pretty much in ignorance of the work of Rowell and Finlayson and each other. From the standpoint of plastics extrusion, the most thorough treatment appeared in 1953 (25). This symposium contained seven papers, five dealing with the theory, experimental behavior, and design of melt screws, one with scale-up of plasticating extruders, and one with heat transfer in extruders. Equations were developed giving the output, die pressure, and power consumption of melt screws in terms of their dimensions, speed, and the melt viscosity. While most of the work was directed toward metering screws, screws of varying dimensions were also considered. At the January 1953 conference of the SPE, three papers (28, 29, 30) that make up a good introduction to the subject were presented.

Melt flow theory



The notion of drag flow is fundamental. Here, however, the material being dragged is a viscous liquid that shears uniformly throughout its depth. The drag flow forces the melt toward he discharge end of the screw. However, the die offers resistance to discharge, so pressure is built up there. This pressure tends to force some of the liquid backward toward the feed end. At the same time, there is an increase of pressure from one turn to the next which causes backward leakage through the clearance between the barrel and the flight land. The result of these three flows is the net output of the extruder. The equation is:

$$Q = Q_D - Q_P - Q_L \qquad \text{(Eq. 1)}$$

In most melt screws it is safe to neglect the leakage flow, Q_L, as a small fraction of the net.

The drag flow and pressure flow

Fig. 1: In the extrusion process softened plastic is forced by revolving screw through heated barrel and out of die

are functions of the screw dimensions and speed, and pressure flow depends also upon the melt viscosity and, of course, the pressure developed.

$$Q = AN - B\frac{\Delta P}{\mu}$$

$$= \frac{\pi^2 D^2 N h \sin \phi \cos \phi}{2}$$

$$- \frac{\pi D h^3 \sin^2 \phi}{12 L} \frac{\Delta P}{\mu} \qquad \text{(Eq. 2)}$$

where D = the average diameter of the screw = the major diameter minus the thread depth, h, inches.

N = the screw speed, rev./seconds.

L = the axial length of the melt zone, inches.

μ = the melt viscosity appropriate to the operating conditions, lb., sec./sq. inch.

ϕ = the lead angle of the screw. A lead distance of one diameter corresponds to a lead angle of about 18°.

ΔP = the total rise in pressure (= pressure at the die), p.s.i.

A and B are lumped constants.

The flow through the die is also a pressure flow and must be equal to Q, since that is the output of the extruder. No matter what the shape of the die is, the discharge through it can be characterized by the equation:

$$Q = k \frac{\Delta P}{\mu} \qquad \text{(Eq. 3)}$$

where k = the die resistance, the value of which will depend on its dimensions, cu. inches.

If Eqs. 2 and 3 are combined, the pressure and viscosity are eliminated. It is clear that considering the extruder as a whole, the output depends only on the screw speed and the various dimensions of screw and die, and not on melt viscosity or pressure developed!

$$Q = \frac{AN}{1 + B/k} \qquad \text{(Eq. 4)}$$

For any particular screw and die, therefore, a plot of Q versus N (operating characteristics) should be a straight line. Such plots, obtained from a 2 in.-dia. screw pumping heavy sirup through three different dies, are shown in Fig. 2, above.

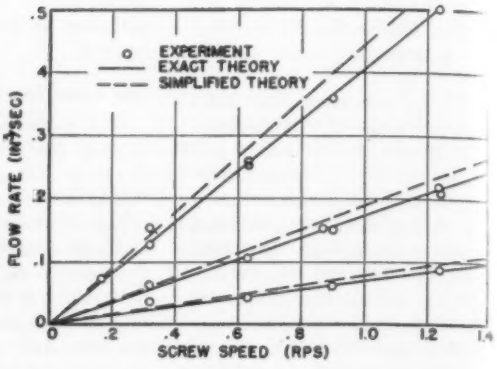


Fig. 2: Operating characteristics for 2-in. screw with three dies, having k values of 1.23, 3.12, and 11.87 × 10^6 cu. in., from top to bottom. The simplified theory gives slightly high values, though leakage was included in the calculations

Screw design

Many assumptions and approximations were made in developing these equations. Equation 4, especially, depends on an assumption that the melt viscosity is the same in the die as in the screw. Since ordinarily the shear rates at these points are different, and since plastic melt viscosities depend on the shear rate, this assumption will not usually be fulfilled. A striking example of how much difference this can make appeared in Ref. 4; however, Eq. 4 serves as a useful guide in spite of its limitations.

The theory also shows how the regulatory characteristics of a metering screw depend on the dimensions. We can summarize thus: regulation is best in screws having small lead angles, shallow threads, and long lengths; unfortunately the output goes down as thread depth or lead angle is reduced (see Eq. 2). A good compromise range for lead angle is from 15 to 25°. It turns out (11) that the same range is useful in the feed zone to achieve good feed rates. It becomes convenient, then, to maintain a constant lead angle over the whole length of the screw and to achieve compression by reduction of thread depth. This type of design also simplifies the machining and reduces manufacturing cost of the screw. In cases where extremely high compression ratios are needed, a combination reduction may have to be used in order to get reasonable output.

At present, the type screw recommended for extrusion of acrylics, nylons, and polyethylene (see pp. 709, 717, and 732) seems to be doing a good job. It will probably serve for most thermoplastics. The present design procedure is to design the melt section (metering zone) according to the abovementioned theory. The feed zone is then made slightly more than ample to accommodate the change in density. The solids feeding theory provides confirmation of its capacity. Measurements made by the authors of that theory show that bulk densities of feeds measured *in the screw* are considerably less than in shipping containers, a fact not generally appreciated. It is the density of the feed in the screw that should be used in calculating the needed compression.

Power requirements

The shearing of viscous materials takes work, and this work appears as heat generated throughout the material. Those areas where shearing is most rapid generally heat up the most. In an extruder the shear rate is fairly uniform, so the turning of the screw generates heat that is distributed evenly through the melt. By the time the melt reaches the metering zone, however, its viscosity has fallen to a level at which the amount of work required to shear the melt is only a small fraction of the total screw horsepower.

Up to the present, no equations have been developed for the work done in the feed section, (though they should be derivable from the feeding equations), and the detailed mechanism of the plasticating zone is not understood. But a simple heat balance sheds much light on power requirements. The feed enters, say, at room temperature (70° F.), and leaves the die at some higher temperature, say 370° F. If its average heat capac-

y over that range is 0.5 B.t.u./lb., °F., and its heat of fusion is, say, 15 B.t.u./lb., °F., then a total of $300 \times 0.5 + 15 = 165$ B.t.u. (or about 0.065 hp.-hr.) must be supplied to extrude each pound of plastic.

A fair rule of thumb to use is this: for every 10 lb./hr. of output capacity, about 1 hp. will have to be supplied by drive and heaters. Some of this can be supplied by preheating the feed, with substantial increases in output and quality (12). This energy may be transferred as heat through the barrel (and screw) or may be provided through mechanical working of the plastic by the screw. Because plastics are poor conductors of heat, very high rates of heat transfer can be realized in extruders only if very high barrel temperatures and/or very long barrels are used. On the other hand, mechanical working supplies the energy evenly at the existing temperature level, thus tending to produce a homogeneous and undegraded melt.

Adiabatic extrusion

In engineering thermodynamics, a sharp distinction is made between heat as such, and work, even though the two are in many ways equivalent. A system, such as an extruder's contents, that neither gives off nor receives heat, as heat, is said to be *adiabatic*. A well-insulated extruder can be made to operate adiabatically (23), but at some sacrifice of versatility.

The custom extruder usually will want to do a large fraction of his heating by mechanical working, using the barrel heaters for final adjustment of conditions. A versatile extrusion setup will also provide for cooling the barrel and perhaps the screw. Improvements in quality have been realized by cooling the screw (2), but at a sacrifice of rate: freezing-out of the melt on the root of the screw in the metering zone reduces the effective thread depth. This may result in better homogenizing, but it definitely cuts down the drag flow. A completely adiabatic extruder becomes especially attractive to the man using it day after day for the same job: once it is designed properly and set up, the operation practically controls itself. The equipment can be quite simple.

Die design

The die is the focal point of the extruder. Here, the melt is forced into something closely approximating its final shape. As has already been mentioned, dimensional uniformity requires the precise metering that is achieved by proper screw design and intelligent operation. Because plastic melts exhibit delayed elasticity (memory), the extrudate cross-section will not be geometrically congruent or even similar to the shape of the orifice, except in the simpler cases (wire-coatings, rods, sheets). This melt elasticity has not been investigated thoroughly enough to reduce die design to a science, but some strides have been made. Laboratory flow data can certainly be used to design dies of simpler shape and to design the screws that are to be used with them. As Eq. 4 demonstrates, the two are intimately associated.

In recent years a number of good articles have appeared on die design. One who is deeply interested in the subject must delve into the field of rheology, and many useful articles on flow properties can be found in back issues of Modern Plastics, Journal of Applied Physics, Journal of Colloid Science, Journal of Polymer Science, Industrial and Engineering Chemistry, and others.

The simplest dies are the spaghetti dies used in making molding powder. Here the laboratory extrusion rheometry applies nicely, and no tight dimensional requirements need be met. Dies for rod extrusion are similar in principle, but usually there are more or less stringent tolerances on extrudate diameter. Pipe dies are more difficult, since both wall thickness and diameter must be controlled, and surface finish is important. In rod and pipe extrusions, the problem of swelling of the extrudate, because of elasticity, is taken care of by having positive take-off devices draw down the extrudate to the desired finished diameter while it is being quenched. Once quenched, swelling ceases. The same technique, basically, is used in monofilament and film extrusion. In extruding pipe, the land length is many times the width of the annular opening, a factor of 30 to 50 being reported as optimum (9). Control of wall thickness increases in difficulty as wall thickness decreases. An effective die design for thin-walled tubing is really two dies in one—the forming die followed by a closely coupled chilling die (34).

The design of cross-head sheeting dies has been discussed in Reference 8, taking into account the non-Newtonian character of plastic melt flow. The principal problem in sheeting manufacture is variation in thickness across the width of the film and in this article equations are given for achieving any desired degree of uniformity by choosing the critical die dimensions on the basis of the melt behavior. K. E. Robbins (18) and H. O. Corbett (22) emphasize the importance of making dies and die fixtures versatile and interchangeable. Robbins also introduced the dam-type sheeting die, a die in which a wide range of thicknesses can be made. An adjustable "dam" behind the die lips provides pressure compensation over a range of flow rates.

It has been shown that if the melt is forced through the die too strenuously, the shear stress may exceed a critical value, about 100 p.s.i., and the extrudate will become rough (15). If the stress is increased even more, the extrudate will tear, even to the point of fragmentation. Much higher rates can be realized if the approach to the constricted die lips is streamlined, (but even then there is a limit beyond which roughness sets in). Streamlining helps not only to prevent roughness, but also helps to prevent melt from "hanging up" in the die. Dead spots in the die eventually become filled with severely degraded polymer that can ruin the product. Vinyls are particularly sensitive in this respect.

Some years ago Fisher pointed out that cross-head extrusion dies, originally developed for wire coating, offer the versatility needed for some interesting special effects (32). Multi-color extrusions can be made by hooking

two or more extruders up to one die. In similar fashion, polyethylene-lined vinyl tubing was extruded in one step. An interrupter in the die permits extrusion of ribbed tubing. And so on. Fisher gives construction details.

Die design recommendations for individual resins will be found in the articles beginning on p. 709 which cover specific materials.

Mixing

Extruders are often used to mix colors, stabilizers, and fillers into the resin. While not as effective for this purpose as intensive (Banbury) mixers, they often serve adequately. Years ago, it was thought that by extending the screw shaft in a long smooth nose or "torpedo" fitting closely in the barrel, dispersion of color particles would be improved. It is now known that the shear stresses attained are not nearly high enough to disperse pigment particle aggregates. However, the long, thin annulus surrounding the torpedo offers tremendous resistance to the discharge of the screws. This means more back flow and more total shear, resulting in better mixing. This added resistance increases the effective length of the melt zone and improves regulation, but with an output penalty. Packs of screens placed in the die before the lips have been used for the same purpose. Today it is recognized that proper design of the metering zone and die eliminates the need for additional front-end resistance. For the purpose of improved mixing, however, a new, helically grooved torpedo has been announced (1). This has the advantage of not offering much restriction while doing a good job of subdividing and recombining the melt stream.

In two papers presented at the Miami meeting of the ACS in April, 1956, criteria for mixing in shear were proposed and equations giving the amount of shear accomplished in an extruder were presented.

These papers, to be published in Industrial and Engineering Chemistry, should provide impetus for some new designs of mixing screws for single-screw extruders.

Multi-screw extruders have long been used for compounding. Recent correspondence (10, 5) indicates there is still much divergence of opinion on their relative merits as compared with single-screw machines. Types having intermeshing screws approach positive-displacement pumps in their metering characteristics, however, and from the regulation standpoint they are excellent.

Recently M. S. Frenkel proposed the "imposed-order" extruder (14), a fancy machine designed for efficient mixing in which the screw diameter (both root and major) alternately increases and decreases. Both barrel and screw have flights. This machine, on which patents have been granted, should do much to stir up thinking on extrusion-mixing.

Extraction-extrusion

Many molding powders contain residual volatiles—water, monomer, solvents—which will cause bubbles, surface roughness, and distortion if not removed before extrusion. One way to do this is to dry them in an oven or hopper-dryer, incidentally realizing the advantages of preheating (12). A second approach is to build the extruder with a vented zone where the volatiles can be flashed off after the plastic has been melted and brought to a temperature well above the normal boiling point of the unwanted volatile matter. The vent may simply be open to the air, or a vacuum may be applied to speed things up and to keep the vapors out of the working area. In most such extruders and in the vacuum screw proposed by Bernhardt (13), the vented zone is rather short, but adequate for removal of up to 5% volatiles from the feed.

The vented screw can be adapted to any extruder with a sufficiently long barrel ($L/D = 18+$), and is by far the cheapest method of venting for an operator who already has an extruder. Careful attention must be paid to the design of the different screw sections.

The twin-screw extractor-extruder of Welding Engineers can have a very long vented zone and is capable of turning out a dry product (bubble-free) even from slurry feeds containing less than 50% solids.

Instrumentation

In years past, extrusion was accomplished without benefit of any but the crudest instrumentation. Today, increasing competition requires high productivity. Good instrumentation not only saves man-hours, but eliminates man-errors. The standard modern extruder is provided with 3-zone heating and cooling, and appropriate controllers. For the sake of knowing what is going on in the extruder, it is wise to have thermocouples in both the melt in the die and the die metal (17). A melt pressure gage (26, 19) in the die is a good indicator of rate fluctuations, and its signal output can be fed into a speed controller. Closer control is the trend in extrusion, as in injection molding.

EXTRUSION OF ACRYLICS

BY C. P. MacDERMOTT*

Extrusion of acrylics into sheets, contour shapes, and rods is taking on increasing importance. Techniques for extruding the three types vary somewhat (see Table I, p. 710).

Extrusion of sheeting

A significant portion of acrylic resins is extruded into flat sheeting to be used either for glazing, for postforming into outdoor signs and displays, or other applications. Whatever the application, however, it is highly desirable to produce sheeting that is: 1) shrink-free; 2) uniformly thick; 3) glossy; and 4) free of surface defects. These properties can be readily obtained by the use of the proper extrusion and take-off techniques.

Shrink-free sheeting

For practical purposes, shrink-free sheet may be defined as that having less than 0.5% shrinkage in either the machine or transverse direction when subjected to the normal heating cycles used during postforming operations. Such extruded sheeting must be prepared by using the least possible amount of draw down. This may be accomplished by allowing the extrudate to sag vertically ½ to 1 in. in the 3 to 5 in. horizontal span between the die lips and the take-off equipment.

The advantages to be obtained by the lack of inherent shrinkage in the acrylic sheeting are: improved uniformity of thickness in the postformed shape and increased resistance to impact and solvent stress crack.

Uniform thickness

During a run, random spot checks on thickness should show no more variation than ± 5% for sheeting from 40 to 200 mils thick. The variation may be either across the sheet or in the machine direction. However, with proper attention to screw design and extrusion temperatures, the caliper variation in the machine direction is usually not significant. With transverse uniformity, on the other hand, additional precautions are necessary to prevent large deviations in the thickness of the sheeting.

Assuming that the die opening has been set to produce the nominal thickness wanted, the caliper variation across the sheet can be checked by observation of the extrudate as it leaves the die. This is true providing the sag recommended for shrinkage control is maintained. As long as the sag across the entire sheet is uniform, acceptable uniformity of thickness can normally be expected in the finished sheet.

If the sag is not uniform in one or two areas across the sheet, it is frequently possible to make corrections by adjusting the zone temperatures in the die. Since the viscosity of acrylic resins varies sharply with temperature, these adjustments must be made carefully or over-control may re-

Draw ratio [3]	1:1	1:1	1:1

[1] Compression ratio = $\frac{\text{Volume of thread in first turn past feed opening}}{\text{Volume of thread in last turn at output end}}$

[2] Lead ratio = $\frac{\text{Distance between corresponding points on successive turns on same flight}}{\text{Inside diameter of barrel}}$

[3] Draw ratio = $\frac{\text{Cross-sectional area of die opening}}{\text{Cross-sectional area of finished (untrimmed) extrudate}}$

sult. For example, the viscosity increases by about 100% when the melt temperature is decreased from 420 to 400° F. An increase in viscosity of the extrudate in any one area across the die will cause that portion of the extrudate to be drawn down to a thickness appreciably less than the remainder of the sheet. A similar decrease in viscosity may cause localized sagging to such an extent as to interfere with the normal take-off procedure.

If an appreciable error has been made in setting the die opening at some point across the die it is unlikely that compensation for the error can be made by changing the die temperature at that point. Adjustments are then required to correct the die opening. These can be made while operating by changing the setting until uniform sag is obtained.

Surface Imperfections

For many applications of extruded acrylic sheeting, it is desirable to have a product that is sparkling clear, with good gloss and without die lines or surface blemishes. To obtain these features, reasonable care in the preparation of the die prior to extrusion should be used. Imperfections in the sheet can be avoided by proper machine operation.

Die lines: The following suggestions are made to prevent the formation of "die lines" (continuous scratch-like lines formed along the surface of the sheeting in its machine direction):

1) The die lands must be pol-

ed to a very high (No. 4) finish, and the die opening setting made without marring the finish. To minimize accidental marring of the finish, it is recommended that the lands be made of a hard steel and then chrome-plated.

2) All of the inside surfaces of the manifold-type die should be polished to at least a No. 10 finish and then chrome-plated. Extreme care must be exercised so as not to mar these surfaces. Because of the unusually long "plastic memory" of the acrylics, a disturbance set up in the melt flowing through the die manifold may remain and appear as a die line even after passage through the die slot and die lands.

3) Care must be taken to prevent contamination of the resin as it is fed to the extruder, since foreign particles may hang up in the die opening and cause die lines. Drums and hoppers should be kept covered during extrusion.

4) The melt temperature of the acrylics in the die should be carefully controlled to minimize die lines. If the temperature is on the low side of the normal extrusion range, the sensitivity of the extrudate to die lines is greatly magnified. If the temperature is too high, incipient "boiling" at the die land is frequently encountered, causing surface bubbles that resemble die lines. As far as the effect of temperature on the severity of die lines is concerned, it is best to maintain the melt temperature as high as possible without encountering the "incipient boiling."

It is in this area of extrusion that the new high-heat distortion acrylics (e.g., Lucite 140[1] acrylic resin) are advantageous. The unusually high upper extrusion temperatures of these materials makes it possible to operate in the range of 470 to 490° F., a point high enough to cause all but the most severe die lines to "flow out" and disappear from the surface of the sheeting.

Other surface imperfections: Surface imperfections other than die lines may, of course, be due to a number of things. One of the more obvious and most frequently encountered is contamination of the resin either prior to extrusion or as it comes from the die. When this contamination consists of very fine, dust-like particles, the result is myriads of small sinks or dimples in the sheeting that are more noticeable than the particles themselves. Such contamination can also be obtained during regrind operations, and it is highly advantageous to do the regrinding in a clean, dust-free area.

Take-off technique

Acrylic sheeting is best extruded using an air quench, and quite a bit of latitude is permissible with the design of the take-off equipment. However, adherence to a few basic principles in take-off technique will result in a product having optimum physical properties and appearance.

The first part of the take-off to come in contact with the hot extrudate frequently consists of a series of rolls, or simply pipes, spaced about 1 in. apart and perpendicular to the direction of extrudate flow. The surface temperature of the rolls making up the first 2 to 3 ft. of the over-all 10 to 20 ft. length of the take-off equipment should be maintained within the range of 100 to 130° F. If the temperature is held much below 100° F., "freeze off" lines across the sheeting are formed. In addition, the sudden quenching tends to magnify the size of sinks or dimples manifested as surface imperfections. If the surface temperature is allowed to go much above 130° F. the sheeting starts to stick to the rolls, resulting either in lines across the sheeting or, if too hot, a complete stoppage of sheeting movement.

In addition to the temperature of the rolls, their surface condition must also be considered. They must be absolutely free of any dirt, grit, or surface imperfections that would cause scratching of the sheeting as it is drawn across the rolls. These scratches have much the same appearance as die lines, although an experienced operator can tell the difference.

Acrylic rod extrusion

In the extrusion of acrylic sheeting, the length of the die land is relatively unimportant, since it is possible with the manifold-type die to produce good sheeting whether the die land is $\frac{1}{16}$ or 2 in. long. The land length assumes a greater importance in forming a good rod, however, and it has been found that a ratio of the land length to rod diameter should be about 7:1 to 10:1. As in the case of sheeting, the inside surface of the rod die must be highly polished to prevent die lines.

There are a number of designs for rod take-off equipment, but the one most widely used consists of a long series of rollers sized to ½ the diameter of the rod being made. The length of the conveyor system is governed by the cooling time necessary to produce a rod that can be handled without bending. The rollers are set at a slight angle to the forward travel of the rod, causing the rod to turn slowly. This constant turning helps considerably in maintaining roundness. In a few instances, a water quench has been used successfully to speed up the cooling process and to provide a hardened "skin" which aids in holding concentricity.

The problem of bubble formation in extruded rod exists to a degree not encountered in sheet extrusion. This is due to the greater thicknesses involved. The vented barrel (with vacuum assist) or the vacuum screw are particularly advantageous in conjunction with rod extrusion, since they will eliminate most causes of bubble formation. The new high-heat distortion Lucite 140 acrylic resin also performs well in rod extrusion even without the devolatizing equipment, since it has a low volatile content.

General extrusion techniques

Melt temperatures: If the melt in the extruder is kept hot too long it degrades, and the extrudate suffers from discoloration, poor surface, etc. The normal melt temperature during extrusion may be considered to be the top safe temperature for a hold-up period of 5 minutes.

Predrying: The equilibrium moisture content of methacrylates at 50% relative humidity and 70° F. is about 0.6 percent. For this reason, the powder should be

dried prior to extrusion regardless of exposure after opening the shipping container. A moisture content of about 0.1% or less is optimum.

A circulating-air oven is adequate for drying. The drying time, of course, depends upon a number of variables, such as original moisture content, relative humidity of air prior to drying, etc. When in doubt, however, a drying period of at least 8 hr. at 175° F. is recommended. A hopper drier set up to give the same amount of drying is also adequate.

Venting of extruder: Drying of the resin may be omitted if a vented extruder is used. A vented extruder will ordinarily operate very satisfactorily on acrylics, and is desirable for many acrylic extrusions in that it will assure an extrudate free of internal bubbles. This is particularly advantageo for rod extrusion.

Barrel, screw, and dies: Sin the decomposition products acrylic resins are not corrosiv a good grade of tool steel is ad quate for the dies. For high fini and longer wear, sometimes th dies are chrome-plated. Barre and screws may be made of con ventional extrusion machine ma terials.

EXTRUSION OF TRIFLUOROCHLOROETHYLENE (TFCE)

BY J. A. JUPA*

Trifluorochloroethylene is a versatile thermoplastic with an unusual combination of outstanding physical and chemical properties. It is a high polymer of trifluorochloroethylene (hereinafter called TFCE) which can be used at temperatures up to 392° F. and as low as −320° F. The material is nonflammable and possesses excellent weathering resistance, zero moisture absorption, toughness, transparency, excellent electrical properties, fungus resistance, and chemical inertness. Molding materials are supplied in the form of plasticized and unplasticized powders. These molding powders for extrusion purposes exist in the form of high-density granules or pellets (60 lb./cu. ft.) or low-density powder (19 lb./cu. ft.). Although both high- and low-density powders can be used for extrusion work, most molding powders are identified by grade numbers, e.g., Kel-F[1] 270, 300, and 500. Where greater flexibility is desired, plasticized material, e.g., Kel-F grade 300 P-25, is most commonly used; the amount of plasticizer could be varied to suit the application.

Type of equipment

Certain general requirements have been set up for extruding TFCE (see Table I, p. 713). More specific details are discussed below.

TFCE has been extruded on most of the commercially manufactured machines. Minor machine modifications specific to TFCE might be necessary to insure high quality of extruded products. For the most part, electrically-heated extruders are used which are able to maintain uniform temperatures between 300 and 675° F. The maintenance of the uniform temperature is most important since the character of the profile is dictated by its thermal history within the extruder. A system of heat control which maintains a constant balance between the heat lost to the plastic melt and the heat introduced by the heating system, would approach ideal operating conditions. The temperature fluctuations should be kept to a minimum in the range of ± 2° F. along the length of the barrel and die. It is particularly important to keep the die temperature constant. An excess of 10° F. at the die can cause excessive material breakdown while a drop of 10° F. gives satisfactory material.

The contact surfaces of the barrel can be Xaloy 306, high chrome-nickel, stainless steel, Duranickel, or chromium-plated steel.

With the exception of Xaloy 306, the contact surfaces for screws should be the same as discussed above for extruder barrel surfaces. Two types of screws have been found to be satisfactory—the conventional full-flighted screws having uniform pitch and increasing root diameter and the metering-type screw with uniform pitch and increasing root diameter.

Compression ratios of 1½ and 2½ to 1, have been most commonly used. The contact surfaces should be smooth and highly polished with a radial clearance of 0.005 in. or less. Provision should be made to keep the hopper zone in the screw area relatively cool. This may be done with air or water. Excessive cooling in this area will place an unnecessary load on the drive mechanism and most likely be accompanied by "squealing."

Excessive heat in the hopper zone will result in premature melting of the TFCE molding powder and be manifested by loss of feed and bridging of the molding powder in the hopper. The hopper should be made of stainless steel or chromium-plated steel to prevent discoloration of extruded profile.

Extrusion rates of TFCE materials are lower than most common types of thermoplastics and lower screw speeds are necessary. Therefore, provisions for screw speeds between 3 and approximately 30 r.p.m. should be considered. Screens are not usually necessary for extrusion of TFCE. However, to minimize the effect of surging and for more complete dispersion of color concentrates, a breaker plate with ⅛-in. holes and screens between 40 and 100 mesh have been successfully employed.

Die design

The materials of construction of the die are similar to those recommended above for the barrel of the extruder with the exception of Xaloy 306. For many rod and tube applications, die dimensions approximately 10 to 15% greater than the nominal size will be satisfactory. This should result in extrusions that have a low degree

[1] Kel-F is a registered trademark of the Minnesota Mining and Mfg. Co. TFCE is also made by Bakelite Div. of Union Carbide Corp. under the trade name "Bakelite."

strain. However, for increased production rates, less critical control problems, and in cases where the higher degree of strain is desired, the drawdown ratio can be scaled up accordingly. The most commonly used drawdown ratio is 3 to 1. Drawdown ratios as high as 12 to 1 have been used for certain types of work. Figure 3, p. 714, shows a straight in-line tubing die; some suggested die dimensions for tubing are contained in Table II, p. 715. To maintain optimum properties in the final extruded piece, the highest temperatures should be concentrated at the exit portion of the die. This is accomplished by extending the die bushing 1 to 4 in. between the die head and using a band heater on this bushing to control the heat independently. It is most important to have very accurate and uniform control of the die temperatures. A minimum number of "spider" legs should be used.

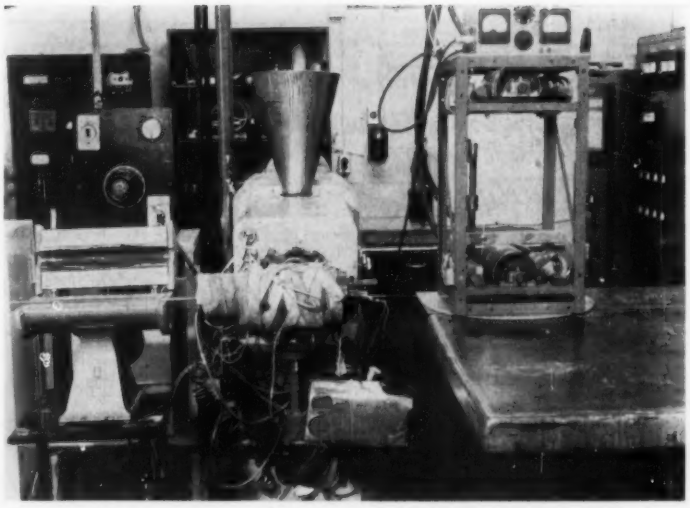

Fig. 1: Manner in which die is mounted in machine and wire heating and cone heating devices are shown in setup above

Wire insulation

The high-melt viscosity of TFCE requires the use of tube-on techniques, rather than the conventional pressure type extrusion methods used on vinyls and other more highly plasticized thermoplastics. The use of the tube-on techniques eliminates the restrictive effect of small die sizes. In this way the die sizes can be increased appreciably and the oversized tube is drawn down onto the wire as it leaves the die.

Considerable progress has been made within the last year on the die design most suitable for wire insulation with TFCE and also some basic principles have been established. Figure 2, p. 714,

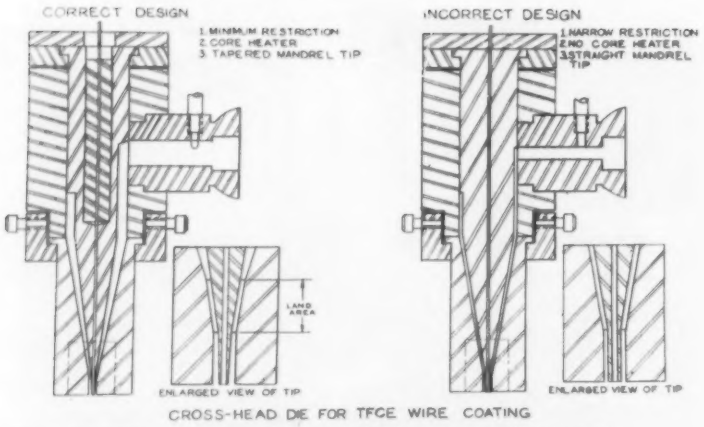

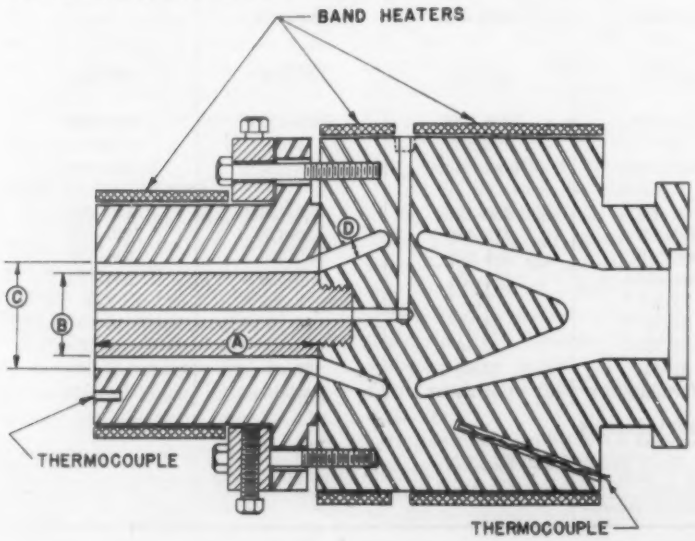

Fig. 2: Comparison of correct and incorrect design for cross-head die to be used for extruding trifluorochloroethylene wire coating

shows correct and incorrect designs. The correct design stresses the minimum restriction to flow within the die to the land area. This allows the use of maximum pressure within the die and the positive movement of material. An enlarged view of the tip shows the land area has been moved back along the mandrel for a short distance and the guider itself has been tapered. The die bushing essentially leaves the land area in a straight line. The use of a tapered tip shortens the length of the cone leaving the die, giving improved centering and lower shrinkage or strain. The use of an internal or core heater is recommended wherever possible. This allows the over-all temperature of the plastic melt to be reduced and minimizes the effect of material breakdown. However, satisfactory work has been done with and without the use of an internal heater.

In the past, vertical extrusion has been recommended. Using the new die design, a shorter plastic cone is obtained and horizontal extrusion is possible. Horizontal techniques fit in with most existing wire insulating setups. For horizontal wire coating, there has been added a device on the entrance side of the die which would maintain the wire temperature close to that of the TFCE plastic leaving the die and a furnace on the exit side of the die to permit normal shrinkage above the transition point (417° F.). The use of a wire heater should not be overlooked. Formerly, minimum quench distances were recommended; that is, it was recommended that the wire be quickly quenched in water as soon as possible after leaving the die. More recent work has shown that a quench distance of three feet or possibly more, results in lower shrinkage on the wire. The lower shrinkage, a maximum shrinkage of 45% or less, does not develop flareback when tested according to the solder-dip test of MIL-W-16878.

All other accessory equipment such as pay-off capstan, spark-tester, and takeup are of conventional design. Figure 1, p. 713, shows the manner in which the die is mounted in the machine and the wire heating and cone heating devices.

Fig. 3: Straight in-line die is recommended for extruding TFCE when production runs are long. Die dimensions are listed in Table II, p. 715.

Operating temperatures

In the final analysis, the actual temperatures used may be ± 25° F. or thereabouts of the suggested temperatures. It is important to have a reasonable temperature differential between various heating zones so that the controlling effect is of a positive nature. The final temperature settings will be determined by the character of the extruded profile. Excessive temperatures are being used when material develops numerous bubbles. The temperatures are too low when the extruded profile is lumpy, rough, or has a snakeskin appearance. The correct temperatures are attained when the extruded profile is smooth, transparent, and clear after it leaves the die. It is most important to use the lowest practical temperatures. At 500° F. material temperature, TFCE will not develop any significant material breakdown in one to two hours. At a temperature of 550° F. TFCE would not suffer any excessive breakdown within a half hour or less. In the neighborhood of 600° F., significant breakdown could take place within minutes. Therefore, it is important to keep the higher temperatures near the

TABLE II: Suggested die dimensions

exit portion of the die where the contact time is reduced to a minimum. As indicated above, material breakdown is a function of the time and temperature, that is, the rate of material breakdown increases with temperature and with time at any fixed temperature.

Product quality

TFCE is essentially a crystalline material. The degree of crystallinity can be modified by various heat treatments. Within certain limits, if a clear transparent tube is required, quick quenching in water is recommended; however, if it is desired to increase the rigidity of the tubing, a more crystalline or more slowly cooled medium is suggested. Normally, cooling the extruded profile in air will serve to increase the degree of crystallinity and the general stiffness of the product. However, a subsequent, prolonged heat treatment can induce further crystallinity. Good clarity by quick quenching can be expected in profile thicknesses up to 1/8 in.; beyond this section thickness, the clarity gradually diminishes to a translucent effect.

The useful life of any extruded plastic article is to a great extent a function of its retained or residual molecular weight. Therefore, minimum breakdown in the extrusion process should be considered a desirable goal. The extent of material breakdown during extrusion can be measured with various devices. In the case of TFCE the ZST apparatus has been found very useful as a quality control device. In this device, a prepared test specimen with a double notch at the center is suspended in a constant temperature chamber with a fixed weight suspended from one end. The period of time in seconds required for this specimen to break is a measure of its relative molecular weight. The higher the value in seconds, the higher the molecular weight; the lower the value, the lower the molecular weight. This device will make it possible to maintain uniform quality of extruded products.

EXTRUSION OF CELLULOSICS

BY H. SEGAL*

The family of cellulosics includes cellulose acetate, cellulose propionate, cellulose acetate butyrate, and ethyl cellulose—all of which are extrudable by the methods which are discussed in the following article.

The cellulosics are generally noncorrosive and the extrusion equipment and dies are usually fabricated of steels selected to provide ease of fabrication and serviceability rather than corrosion resistance. Recommended materials of construction are as follows: barrel—any superhard alloy; screw—machine steel with top of flights hard surfaced or with screw heat treated to obtain additional surface hardness; dies —carbon steels or hardenable steels where such materials are desirable.

* Development Project Mgr., Celanese Corp. of America, 200 Ferry St., Newark, N. J. References were prepared by the editors.

Screw design

The screw design shown in Fig. 1, below, has proven suitable for cellulosics extrusion. It has a 1.7:1 compression ratio which is attained by varying the root diameter. With this design it is necessary to provide internal cooling in the screw and a screen pack containing at least one 30-mesh screen to minimize the effects of a tendency for extruder surging, particularly at the higher screw speeds. It is hoped that improved screw design will eliminate the need for these correctives. Higher compression ratios have been used but of themselves have not yielded any benefit. Output rates do fall off as compression ratio is increased.

Extrusion conditions

See Table I, p. 716.

All cellulosics are mildly heat sensitive and require some care in handling. This sensitivity is time–temperature dependent and, accordingly, there is a maximum temperature limit for their processing. The flow path through the gate and die must be streamlined to prevent stagnant areas where thermal degradation would occur.

Flow properties: Cellulosics for extrusion can be manufactured in a wide range of flow properties by varying the formulation. The choice of resin is based on the functional requirements of the end product being manufactured and/or equipment limitations.

Operating temperatures: Figure 2, p. 716, shows the relationship between average extrusion temperatures and flow properties of cellulose acetate. Similar curves could be prepared for the other cellulosics. The minimum operating temperature is a function of the softening point and the maxi-

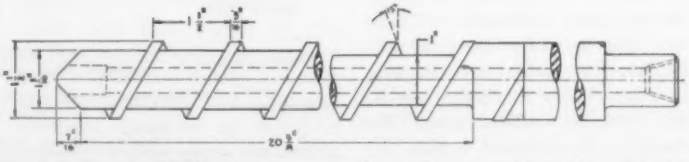

Fig. 1: Sketch of 1.7 compression ratio screw for 1 1/2-in. extruder

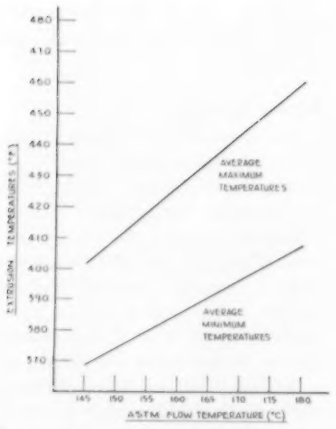

Fig. 2: Relation between acetate extrusion temperatures and A.S.T.M. flow temperatures

mum operating temperature a function of flow properties of the material.

It is very important that the proper operating temperatures are used. These may have to be determined experimentally for each new grade of resin. High temperatures tend to degrade the resin and cause decomposition products which may discolor or disfigure the extruded product. Low temperatures produce poor surface finish and poor physical properties.

Predrying: Since cellulosics absorb moisture, it is necessary to dry the pellets prior to or during extrusion. The latter technique involves the use of a vented extruder which can remove volatiles in the course of extrusion. Regardless of the means employed, the extrudate must not contain over 0.3% water or the product will show surface defects.

There are several acceptable drying methods. These are: tray drying in an oven, belt drying in an oven or under infra-red lamps, continuous rotary-tray drying, and hopper drying. The last method involves a continuous system that forces warm dry air up through a large hopper above the extruder feed section. There are also specially designed extruders that contain devolatilizing sections. These machines can be fed undried pellets since the moisture is removed within the extruder.

Drying time is generally from ¾ to 3 hr. at 140 to 170° F.

Purging routine: Continue extrusion at minimum rates until all temperatures fall approximately 50 to 70° F.

Future development

The principal problems that still face the cellulose plastics extruders, and probable solutions are as follows:

1) *Increased output.* This is important because it allows increased production capacity without the expenditure of additional capital. The solution to this problem probably lies in better screw design, in arriving at optimum operating conditions, and in some cases in better design of take-off equipment which is used with the extruder.

2) *Improved uniformity.* Dimensional variation in extruded cellulose products are partly a function of the variability of the extruder operating condition. In addition, extruder surging with the cellulosics, which is not associated with stability of extruder conditions, is also a factor. There

B. Operating conditions	
Melt temperature at die, °F.	This is a function of flow range of the resin being used.
Approx. melt pressure at die, p.s.i.	50 to 200 depending upon die exit restriction
Is screw cooled?	Yes
Medium	Water or water and steam
Temperature of medium, °F. or wattage in 150 lb./hr. screw	Room temperature to 100°F
Is feed preheated?	No—except as might result from drying prior to extrusion (See text on "Predrying," left.)
Metal temperatures, °F.	
Rear cylinder	These all depend on flow range of the particular resin being used.
Halfway along cylinder	
Forward cylinder	
Die	
Is extrudate water quenched?	No
Draw ratio[3]	1:1 = 15:1

[1] Compression ratio = $\frac{\text{Volume of thread in first turn past feed opening}}{\text{Volume of thread in last turn at output end}}$

[2] Lead ratio = $\frac{\text{Distance between corresponding points on successive turns of same flight}}{\text{Inside diameter of barrel}}$

[3] Draw ratio = $\frac{\text{Cross-sectional area of die opening}}{\text{Cross-sectional area of finished (untrimmed) extrudate}}$

are many uses for cellulosic products that cannot presently be filled by extruded materials because of the lack of uniformity.

Those conditions which may provide the necessary improvement are more uniform control of screw rotation; cylinder, gate, and die temperatures; melt temperature; take-off equipment speeds; and, again, improved screw design.

3) *Surface improvement.* In addition to gels, other surface deficiencies are die lines, pock marks, and blush. Reduction of these defects may possibly be accomplished by better die design and by further progress in development of take-off and melt cooling equipment.

EXTRUSION OF 66 NYLON

BY KAREL G. TOLL*

Nylon is the generic name for a group of thermoplastic materials defined chemically as polyamides. They are characterized generally by extreme toughness, strength, and resistance to heat, chemicals, and abrasion. The several different types of nylon, though related, differ in chemical composition and have different heat resistance, solvent resistance, flexibility, and fluidity at processing temperatures. Typical of this variance are the various Zytel[1] nylon extrusion compositions listed in Table I, p. 719. Other compositions may be used at times, but they are usually similar in characteristics to one of the types which are listed in the table.

The higher-melt-viscosity resins, e.g., Zytel 63 and especially Zytel 42, can be readily handled by the general thermoplastic extrusion techniques. On the other hand, the low-melt-viscosity types, Zytel 101, 31, and 33 have characteristics which require special consideration with regard to extrusion processing.

Extrusion equipment

A typical extruder for nylon resin can be broken down into the following list of important features:

Barrel and heating equipment: Long barrels are desirable for the extrusion of Zytel, because they provide greater heat-transfer area to facilitate melting of the resin. The ratio of the length of the barrel to its diameter should be at least 16:1. A ratio of 18:1 or 20:1 is even better.

Some extrusion operations involving Zytel require temperatures as high as 600° F.; consequently, electric heat is preferred. Oil heat is generally not practical for use in this temperature range.

Normally the hopper section does not require water cooling; however, when necessary to protect the bearings, the minimum amount of water possible should be used.

Hopper feed throat: In order to prevent excessive wedging of resin particles between the flight land and barrel wall, the direct overhead or tangential-type feed throat should be used. The undercut-type feed throat is not recommended.

The screw: A screw of the metering type, with half-turn compression, as shown in Fig. 1, p. 718, is recommended for the extrusion of Zytel. This is a constant-pitch screw, divided functionally into three sections.

The last four flights of the screw comprise the metering section. This section pumps the melt at a uniform rate, and generates sufficient pressure to force it through the die. The channel is shallowest in this section.

The dimensions shown in Fig. 1 are offered as recommendations for typical conditions, and should not be regarded as optimum for all extrusion operations.

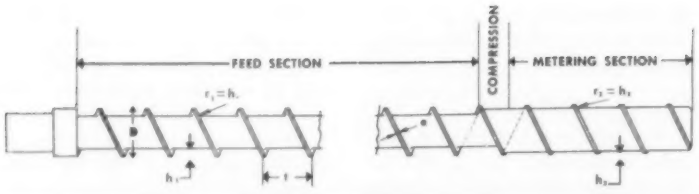
Screen and breaker plate: A breaker plate and two 80-mesh screens are normally used to filter out foreign matter.

Extrusion operation

Drying: All Zytel molding powders are hygroscopic; they readily absorb moisture from the air. The exposure of Zytel to the atmosphere for as little as 30 min. can result in the absorption of sufficient moisture to impair the extruded product.

Zytel molding powders, particularly Zytel 42, can be fed directly from the can to the extruder hopper. It is important, however, that contact with the room atmosphere be minimized. The cans should not be opened unless they are to be loaded at once, and the hopper itself should be provided with a tightly fitting cover. It is generally good practice to keep the amount of resin in the hopper below the amount needed for one hour's running. Excessive moisture in granular Zytel is indicated by bubbles or frothing in the extrudate. These symptoms, however, may also be caused by overheating.

For re-work material or unusual extrusion conditions such as elevated temperatures or long hold-up time, it is necessary to dry Zytel prior to extrusion. The drying procedure, which involves an air-circulating oven at 175° F., is described in Du Pont Bulletin X-39.



Extruder barrel - temperature profile: The temperature-control point in Zytel extrusion is the melt temperature as indicated by the stock thermocouple (7).[2] This indicated temperature is controlled by regulating the extruder barrel temperatures. In order to minimize temperature spread in the melted plastic, a uniform barrel-temperature profile is maintained. With an 18:1 barrel length and a properly designed screw, the barrel temperature should be only 10 or 15° F. higher than that of the melt. The

die and adapter temperatures should maintain this controlled temperature. This is done by controlling die temperatures at about 5° F. above the stock temperature.

The foregoing procedure is designed to deliver the extrudate with a narrow temperature distribution which minimizes localized over-heating or cold plugs.

Types of extrusion

Wire coating: As a primary insulation on small wire, Zytel can be applied at very high speeds and in very thin coatings. A rate of over 1600 ft./min. has been achieved with suitable take-off equipment, and a thickness of as little as ½ mil is possible. When nylon is applied as a primary insulation, good adhesion between nylon and wire can be obtained by preheating the wire by flame or electrical heating. Smaller wires can be coated while passing vertically downward into a quench bath. The air gap between the die and the water level of the quench bath should be small—usually ½ in. or less. For larger wire, or where equipment dictates, horizontal operation has been found to be best.

A cross-head and die assembly is generally used for coating wire with nylon. A typical cross-head is shown in Fig. 2, p. 720. Vacuum is applied between the wire and guider tip in order to pull the flowing cone of plastic close to the die. In this way, a smoother coating is achieved, and adhesion is improved. The annular space between the guider tip and the die, at the point where the molten nylon is extruded upon the wire, should have a thickness of between five and eight times the desired thickness of the coating on the wire. The wire passes through the head faster than the molten resin is fed upon it, and the thickness of the layer of resin is thereby reduced as it is deposited on the wire. Thus, the thickness of the coating is controlled by both the output rate of the extruder and the wind-up speed of the wire. Following the quench bath the wire is tested for breaks in the insulation.

The wire coating technique is covered in detail in Du Pont Bulletin WC-2.

Tubing: Tubing is extruded from nylon by the general method employing a cross-head die with an end-supported mandrel which is probably best for tubing extrusion.

In the extrusion operation, air or nitrogen under regulated pressure is supplied through the mandrel as an internal support for the extruded tube. This regulated pressure within the tubing can be varied to produce a variety of diameters and wall thicknesses from a single die. The size of tubing from a given die is governed by extruder output, take-off speed, and internal gas pressure.

Where burst strength is a paramount consideration the die size should be such that the draw-down is 3:1 or less. Draw-down in this case is defined as the ratio of the cross-sectional area of the die opening to the cross-sectional area of the tubing.

Shape extrusion: Zytel 42 is a higher-viscosity 66 nylon resin tailored specifically for extrusion of shapes, tubing, film, and sheet, and for blow molding. The extrusion of shapes from this resin can be accomplished by either horizontal or vertical extrusion into a water-quench bath. The flexible, more complex shapes are generally suited to vertical extrusion, while the heavy, less flexible sections are more readily handled using a horizontal quench bath. The horizontal technique is similar in setup to that typically used for the tubing extrusion.

The variables controlling the shape and size of an extruded

profile are: dimensions of the die orifice, extruder output, extrudate temperature, take-off speed, and air gap (distance between die and quench water).

Film: In the extrusion of film, the machine and die should be preheated to the temperature range recommended for extrusion of the particular composition (Table I, right). After extrusion is begun, the temperatures can be adjusted until desired flow properties are obtained.

The method of handling the film varies with the type of nylon because of variations in fluidity, in strength of the molten film, and in crystallization characteristics.

Zytel 42 is the resin most easily extruded into film. Because of its great melt strength the extrusion can be run with a 2- to 3-in. air gap. This process is illustrated in Fig. 3, p. 720. The extrusion of the more fluid types such as Zytels 31 and 101 is also accomplished in the same manner, but greater precautions are required in the handling of the quench step. The bath must be so arranged that the water level is maintained within about ¼ in. of the die. Since the bath is so close to the die, it is necessary that the former be so constructed and supported that 1) there will be a minimum number of ripples on the surface, and 2) ripples are not reflected by the tank sides.

The flexibility and transparency of nylon film of given thickness are affected by chilling rate. Quenching in cold water tends to make the film more transparent and flexible, while hot water makes it more opaque and stiffer. This sensitivity to temperature of the quench water makes it necessary that the bath have good circulation to prevent the development of localized areas of hot water that will cause streaks and spots on the sheet. At the same time, however, this circulation must not cause impingement of streams of water on the uncooled film.

At this stage, nylon is sufficiently fluid that any strong movement of water will cause unwanted wrinkles to form in the film.

The film is pulled by a pair of driven rubber rolls. The rate at which these rolls are turning with respect to the rate at which the film is being extruded will determine what the final caliper will be. Ratio of the initial cross-section to that of the finished film is called the draw ratio.

Following the pull rolls is an edge slitter. This may be of a razor-blade type, but a shear-type trimmer is preferred. Trimming is necessary to remove the slightly heavier section at the edges. This permits an even wind-up. Winding may be accomplished on either an axial- or a surface-type of wind-up roll.

The more viscous and slower-setting Zytel molding powders such as Zytel 63 and 69, and modifications of these, develop a tacky surface when extruded into a water bath.

The chill roll should be as close to the die as possible. This film must be trimmed, too.

Paper coating: All of the various nylons can be extrusion-laminated onto kraft paper and other substrates, using essentially the

TABLE I: Extrusion of Zytel nylon molding powders

Code	*Extrusion temperatures*	*Remarks*
	°F.	
Zytel 42	500-600	High melt viscosity—for shapes, tubing, and blow molding Most heat-resistant, toughest, and most rigid nylon
Zytel 101	500-600	Low-melt-viscosity resin used for rod and tubing—comparable to Zytel 42 in properties
Zytel 105	500-600	Black composition with excellent weathering characteristics; comparable to Zytel 42 in general properties
Zytel 31	450-500	More flexible, more moisture-resistant than Zytel 42
Zytel 33	450-550	Heat stabilized Zytel 31
Zytel 63	450-550	Extrusion grade of flexible type; flow characteristics comparable to conventional thermoplastics
Zytel 69	450-550	Comparable to Zytel 63, with superior resistance to flexural fatigue
Zytel 211	450-550	Polycaprolactam

TABLE II: Symptoms and possible causes of trouble in extrusion of nylon

Symptoms	*Possible cause*
Bubbles	a) Moisture in resin; drying required b) Temperature too high (Zytel may decompose and discolor) c) Low output—excessive hold-up time in the machine results in decomposition
Bridging—loss in output	a) High rear barrel temperatures b) Improper screw design
Extruder overloading	a) Low extrusion temperature especially at breaker plate b) Improper hopper feed throat design c) Improper screw design

same die recommended for the extrusion of film. With most substrates coated in commercial size equipment, adequate adhesion of the nylon film can be obtained in thicknesses of 1 mil or heavier.

The lamination is accomplished in standard equipment used in extrusion coating of substrates with polyethylene. The resin is extruded through the film die immediately ahead of the nip of the pressure and chill roll. The jaws on the die differ from those used in unsupported film extrusion in that the lips have been extended to reduce the air gap between the die and roll nip to a minimum. The pressure roll is a rubber roll with a Shore Durometer hardness of about 60 that is held against the chill roll mechanically, hydraulically, or pneumatically. For normal coating operations a force of 60 lb. per linear in. of roll length is adequate. The chill roll required has the same design as that used for film. This roll cools the laminate, regulates the thickness of the coating by controlling linear speed of the substrate, and plays a large part in determining the surface character of the finished coating.

It is usually necessary to trim the edges of the laminate to remove the "beading," or thickened edges of resin in order to obtain satisfactory roll-up. These heavy edges are due to the necking-down of the film which occurs as the film is drawn. The trimming operation can be easily performed by means of a rotary-type trimmer. This is a spring-loaded, hardened steel disk.

The uniformity of caliper across the die can be regulated either by making adjustments on the die jaws, or by regulating the temperature in the various zones of the die. A better approach, when possible, is to design the die to produce uniform regulation with so that a minimum of on-stream adjustments will be required.

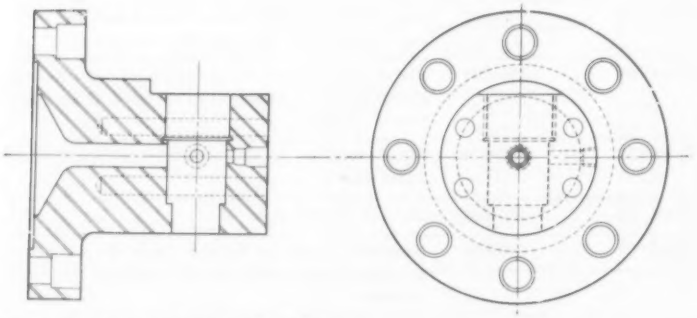

Fig. 2: Cross-head die for extrusion of nylon

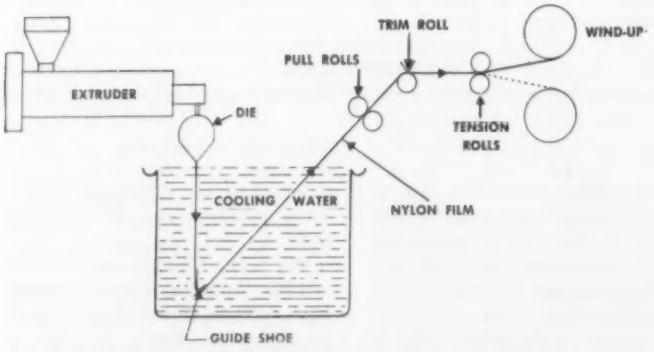

Fig. 3: Assembly for extrusion of film from Zytel 42, 101, and 31 nylons

Cleaning nylon from extruder parts: Nylons are most readily cleaned from extruder parts by burning off the plastic in a "nylon burn-out furnace" (900° F.); where this furnace is not available, the following is done:

After the extruder has been shut down, the screw is removed from the barrel. While the screw is still hot, it is scrubbed with a wire brush and copper mesh. This operation is facilitated if, when shutting down the extruder, the screw is allowed to turn for a short time after the resin supply is cut off. Thus, the screw can force the remaining resin toward the front of the extruder, and thereby purge itself.

With heat still on the barrel, a boiler-tube brush wrapped with copper mesh is pushed in and out of the barrel several times. More copper mesh is then added, and the brush is used again. This procedure is repeated until the barrel shines. A light over the hopper will generally permit good visual inspection of the barrel. The face of the barrel can be cleaned with a wire brush while the machine is still hot. Smaller die parts, bolts, etc., are most easily cleaned by using a hand torch. This operation is followed by wire brushing.

EXTRUSION OF POLYCAPROLACTAM NYLON

BY T. R. VON TOERNE*

Polycaprolactam nylon is a polymer based on the six-carbon-containing molecule, caprolactam, and hence is often referred to as "nylon 6," or "type 6 nylon." It possesses the usual advantages of nylon: high strength, abrasion resistance, light weight, solvent resistance, self-lubrication, and high melting point. In addition, available polycaprolactam nylons offer a number of other advantages in the form of high impact strength, low processing temperature, good dimensional stability, a unique and controllable crystalline structure which can be used to vary the physical properties of extruded parts, and excellent colorability, either during or after extrusion.

The relatively high melt viscosity of certain polycaprolactam nylons facilitates the extrusion of relatively thick films, tapes, small-diameter rods and tubing, and special shapes. In addition, this high viscosity makes these nylons particularly suitable for such applications as the blow molding of bottles.

Extrusion conditions

See Table I, p. 722.

Extruder: Any extruder of sufficient heat capacity to permit continuous operation in the temperature range of 450 to 550° F. is suitable for extruding polycaprolactam nylon. In general, oil-heated extruders are only marginally adequate for even low extrusion rates and an electrically-heated extruder is therefore preferable.

The barrel of the extruder should have at least three heating zones, each equipped with a separate temperature controller, to give the desired temperature profile. The overhead hopper feed throat is preferable. An Xaloy 307 liner is recommended for the barrel.

A metering-type, screw, constant pitch, with either a sharp compression or gradual compression over one to three flights, is recommended for the extrusion of polycaprolactam nylon. Figure 1, p. 723, offers recommended dimensions for this type of screw. Recommended material of construction for the screw is SAE 4140 steel or equivalent, with properly hardened flights.

Temperatures: Polycaprolactam nylon can be extruded over a range of melt temperature between 450 and 550° F., though a range of 450 to 500° F. is recommended for most extrusion work. The machine temperature should be adjusted to obtain the desired melt temperature. A thermocouple for measuring the melt temperature is therefore very desirable in the flow passage of any die head.

If the melt in the extruder is kept hot too long, it degrades and the extrudate suffers from discoloration, brittleness, poor surface, etc. Top safe temperature for 5-min. exposure is 575° F.

Pressures: The proper melting of polycaprolactam nylon requires a sufficient pressure at the discharge end of the screw to insure a uniform homogeneous melt. This pressure depends upon the type of polymer chosen for the application as well as the maximum anticipated throughput requirement. Generally, a pressure of 500 p.s.i. at the lowest throughput will insure satisfactory operation. The building up of this pressure can be accomplished by either: 1) screenpack; 2) die design; or 3) a combination of these two. A pressure gage should be installed at the entrance to the die if possible. Figure 2, p. 723, illustrates one arrangement of a pressure gage in a straight delivery head. The melt thermocouple is also shown.

In cases where no pressure gage is available, a screen pack of 1-20, 1-60, 4-100's, 1-60, 1-20, is adequate for most applications.

Predrying: Most polycaprolactam nylons are supplied in hermetically sealed airtight containers at a moisture content of less than 0.2%, so that normally it is not necessary to dry the material.

Up to approximately ½ hr. (depending on humidity) after opening the shipping container, the molding powder can still be extruded without predrying. For powders that have exceeded this limit, drying times will range from 3 hr. to as much as 16 hr. at 175° F. A vacuum drier or dehumidified oven is preferred to a conventional air-circulating oven for drying nylon. Maximum humidity of air in the dryer should be approximately 60 grains of moisture per lb. of dry air. If a vented extruder is used, it is possible to omit drying if pellets have absorbed only a slight amount of moisture (less than 0.75%). Pellets with more than 0.75% should be dried.

Polycaprolactam nylon scrap can be re-used after drying. The drying time will depend on the amount of moisture absorbed.

Die design

The general principles of good die design that apply to the extrusion of most thermoplastics apply to the extrusion of polycaprolactam nylon. All flow through the die should be streamlined. Areas of stagnation should be avoided since excessive polymer residence time will result in degradation.

Die lands should be long enough to result in a back pressure of at least 500 p.s.i. at the discharge end of the screw. All inner surfaces of the die should be either chrome-plated or of a polished, corrosion-resistant steel.

Figure 2, p. 723, illustrates a typical straight delivery mandrel and die arrangement for extruding tubing.

External setup

Cooling: The rate of cooling of a polycaprolactam nylon extrusion will significantly affect the

[6] Draw ratio = $\frac{\text{Cross-sectional area of die opening}}{\text{Cross-sectional area of finished (untrimmed) extrudate}}$

properties of the final part and careful consideration should be given to the method employed.

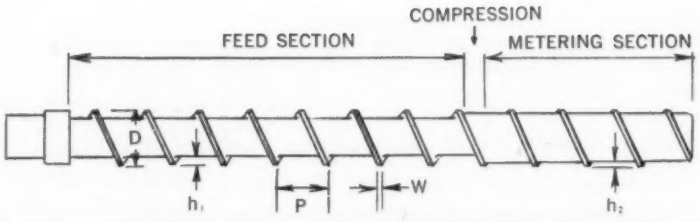
Essentially, three methods of cooling are used: 1) water bath; 2) air; and 3) contact with cooled surfaces.

Most extrusions can be satisfactorily cooled by tap water. In many cases, however, it is desirable to use a less rapid quench to prevent void formation in heavy sections or to obtain certain desirable properties. All other conditions being equal, quenching in hot water (175° F.) will significantly increase the 1) tensile strength, 2) flexural strength, 3) stiffness, and 4) opacity of the extruded part as compared with a cold-water quench. The more rapid the quench, the more flexible and transparent the part will be.

Postforming: As polycaprolactam nylon is a crystalline material having a sharp melting point, the postforming fixtures must be located so that forming can be done within the first 3 to 6 in. in the cooling bath. Contoured plates, rollers, or guides are required to guide the extrusion and

maintain its desired shape as it is solidifying. This is usually the most important, and frequently the most difficult part of the extrusion operation.

Where water cooling is used, it is necessary to maintain a smooth uniform flow of water at the point where the extrusion enters the water. If this is not done, localized boiling will result which will cause surface imperfections on the extrusion. When cooling extruded tubing, the water level should also be precisely controlled to minimize fluctuations in tubing diameter. This is usually best and most simply done by means of a large adjustable overflow weir at some point along the cooling tank.



Types of extrusion

Polycaprolactam nylon such as described above can easily be extruded into tubing, pipe, wire covering, rod, tape, film, and special shapes.

The extrusion of tubing can be done either vertically or horizontally, although horizontal extrusion is generally the simplest. A water tank 10 to 20 ft. long, the longer length being required for higher extrusion rates, is used for cooling the tubing. Contoured plates, guides or rollers are needed to guide and shape the tubing as it is being cooled. A set of motor-driven rolls or belts can be used for pulling the tubing from the extruder die through the cooling tank. A coiler is recommended for winding the tubing into coils for ease of handling.

The extrusion of small rod, special shapes, and small tape can be handled much the same as tubing. The guide fixtures should be shaped to help form the particular contour being extruded. Large-diameter pipe extrusion will require either a water-cooled, extended mandrel or a vacuum-type calibrating unit to maintain roundness of the pipe.

Standard wire insulating equipment can be used in covering wire with polycaprolactam nylon. When the latter is used as the primary insulation, it is best to preheat the wire to approximately 325° F. to obtain good adhesion. The preheating can be accomplished with a resistance heater.

Fig. 1: Recommended screw dimensions for extrusion of polycaprolactam nylon

The extrusion of polycaprolactam nylon film can be accomplished by extruding through a slit die into either a water bath or onto a chill roll. The chill roll cooling method produces a clearer and smoother film. Nylon film can also be produced by the conventional blowing method from a tubular die. Standard film haul-off and wind-up equipment with some modification can be used for nylon film extrusion.

In changing material, the following procedure is recommended: 1) Heat machine to 475° F., 2) when nylon drools from die, start screw and starve feed new material into throat, 3) use full feeding when nylon

Fig. 2: Typical die and mandrel arrangement for extruding nylon tubing

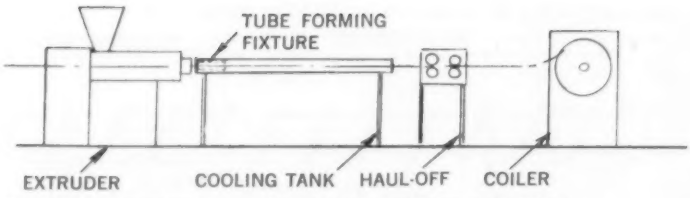

Fig. 3: Set-up for extrusion and take-off of polycaprolactam nylon tubing

emerges from die in steady flow, 4) extruder is ready for running when extrudate is clear.

Maintenance

The cleaning of the extruder can be simply accomplished by shutting off the hopper supply and running the screw until no more material emerges from the die. The head and dies are disassembled and the nylon removed with a stiff wire brush while the parts are still hot. As the hot screw is gradually pushed from the cylinder, the molten material is removed with a wire brush. A wire brush mounted on a drill motor is used to clean the cylinder while it is still hot.

The time for the above procedure can be reduced by purging the machine with a few pounds of polystyrene. The polystyrene is more easily removed from machine parts than the nylon.

A small torch can be used for melting or burning the nylon from the tools and extruder parts in the event the nylon has cooled sufficiently to prevent removal by wire brushing.

EXTRUSION OF TETRAFLUOROETHYLENE

BY WALLACE B. THOMPSON, JR.*, ROBERT E. STABLER*, L. THOMAS BUNN*, and DELBERT N. DeYOUNG*

Tetrafluoroethylene resin (Teflon[1]) offers a unique combination of properties of particular importance to the chemical and electrical industries.

Early in the resin's history, the combination of thermal stability and chemical inertness indicated that Teflon tetrafluoroethylene resins could be used more advantageously than other materials for: 1) making tubing and hose to convey corrosive liquids having a wide range of temperatures and 2) for high-temperature wire insulation.

Initially, limitations were imposed on the production of these forms because the resin could not be melt-fabricated even at temperatures above its crystalline melting point of 620° F. (327° C.). Experimental work in Du Pont laboratories, based on the use of Teflon 6[1] tetrafluoroethylene resin, resulted in the development of a simple and unique technique for overcoming previous limitations.

This technique is based on the blending of an extrusion aid with the tetrafluoroethylene resin and preforming the mixture to a cylindrical billet by compression at 100 to 300 p.s.i. pressure for use in a ram-type extruder. The composition is forced through a forming die by the ram, the extrusion aid is vaporized (at 200 to 575° F.), and the extrudate is sintered and cooled as finished tubing or wire insulation.

Sieving the resin through a 4-mesh screen is recommended prior to blending with the extrusion aid or lubricant. Since excessive working is deleterious to the polymer at this point, the sieve should be vibrated just long enough to allow most of the fine powder to pass through the screen.

Preparation of compound

The addition of extrusion aids to the resin provides compositions which can be extruded at reasonable pressures. The main requirements of a good extrusion aid are: 1) ease of incorporation into the resin and 2) complete and rapid volatilization below the sintering temperature with little or no carbon formation.

VM&P grade naphtha[2] is recommended for general use as an extrusion aid. White oil has also been used extensively for this purpose.

The steps in compounding are as follows:

1) Provide a clean, dry container of suitable size and proportions with a tight closure. For a 1000-g. batch of Teflon, a 1-gal., wide-mouth bottle is a suitable container.

2) Weigh the required quantity of sieved tetrafluoroethylene resin and pour it into the container. Add the weighed quantity of extrusion aid, taking care that the liquid does not wet the walls of the container. The ingredients should be weighed with a precision of at least ±0.5%, preferably ±0.2 percent.

3) As soon as the extrusion aid is absorbed, close the container and shake to minimize adscrip-

[2] VM&P naphtha of specific gravity 0.735 to 0.749; boiling range 194 to 248° F.

tion of the liquid on the container walls.

4) Place the container on a suitable rolling device. (For a 1- or 5-gal. bottle, 20 min. at 15 r.p.m. is recommended.)

5) Seal the container with tape and store the blend for 24 hr. to allow a uniform distribution of the extrusion aid throughout the powder.

The amount of extrusion aid which is required varies with the type of liquid used and the geometry of the extruder. Some experimentation will be required to determine the optimum conditions. Generally, 19 to 25 parts per 100 parts of resin are needed. Adequate precautions should be taken to avoid fire when using naphtha.

Preparation of preform

To prepare the preform, a quantity of the blended composition is compacted in a cylinder which has a core. The dimensions of the cylinder should allow for a 20- to 30-mil radial clearance between the preform and the walls of the extruder cylinder and its mandrel. It should also be at least 2¼ times as long as the preform since the compression ratio of the compounded resin is about 2.25:1.

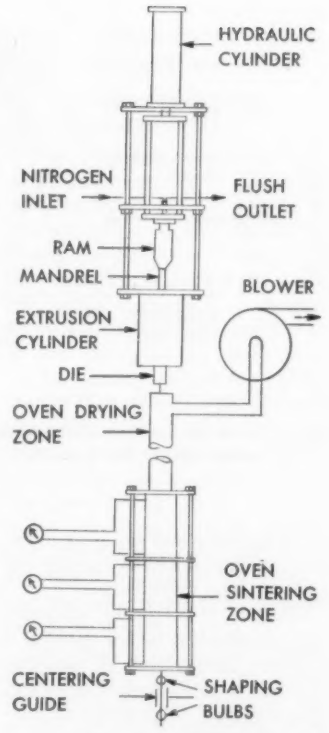
A weighed quantity of the blended material is poured into the cylinder with care to assure even distribution of the powder around the mandrel.

After inserting the closure plug in the preform cylinder, pressure should be built up to about 100 to 300 p.s.i. on the stock over a period of about 3 minutes. The peak pressure should be maintained for about ½ min. and the pressure slowly released. Great care should be used in pushing the preform out of the die.

Tubing extrusion equipment

The basic equipment (see Fig. 1, above) used for the extrusion of tubing from compounded resin consists of a ram, a mandrel over which the ram travels, a cylinder, and a die, all supported on a frame.

A hydraulic piston is preferred as a device for driving the ram, although a screw-jack has been successfully employed to drive small-diameter rams. Equipment capable of providing 10,000 p.s.i. at the ram face should be adequate for most applications.



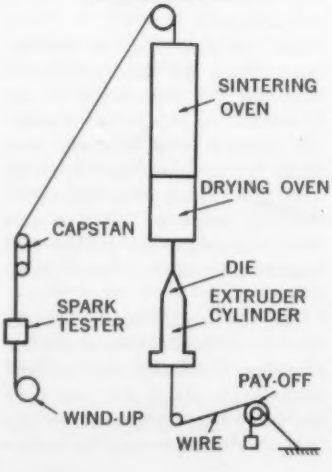


Fig. 1: Basic equipment for extruding thin-wall tubing of Teflon tetrafluoroethylene

For small tubing, the extruder may be either horizontal or vertical, but for tubing more than 1 in. in diameter, it should be vertical. The mandrel forming the bore of the tubing can be straight or tapered at the approach to the die land. The die is normally tapered from the diameter of the cylinder down to the size required for the tubing.

The die land should be long enough to prevent curling or swelling of the extruded piece and to provide enough back-pressure to form a dense product. Table I, p. 724, lists recommendations for land length and die taper angle.

Fig. 2: Basic equipment for extruding wire insulation from tetrafluoroethylene

Tubing extrusion operation

The extrusion process is carried out on a batch basis. The machine must be stopped after each preform has been extruded and a new preform inserted.

In starting up an empty extruder, a tube 2 to 3 in. long, and carefully machined to the proper size, should be inserted in the die land from the discharge end of the die. It should fit snugly since it serves to center the mandrel with respect to the die body. When the stock of resin flows into the annular die land, the stock itself holds the mandrel in a centered position and pushes the positioning tube or centering ring out of the die.

The pressure required for extrusion will vary, depending on machine design and processing conditions. Relatively high pressures are required if the concentration of extrusion aid is low, if the taper angle of the die is relatively large, if the land below the orifice is long, or if the ratio of the cross-section of the preform to that of the product is large.

If the pressure required is too high, the capacity of the machine may be taxed or the tubing may be excessively oriented so that it tends to develop longitudinal splits. If the extrudate is produced under too low an extrusion pressure, it may be weak and porous. This can be corrected by reducing the amount of extrusion aid used or by altering the die and cylinder geometry to increase back pressure.

Drying and sintering of tubing

The tubing is first heated for a sufficient length of time to evaporate the extrusion aid. Initial oven

temperatures, only slightly higher than 200° F., are used for thick cross-sections. Temperatures up to 575° F. can be used for thin walls (such as 15 mils). The tubing temperature should reach 700 to 750° F. in the sintering zone.

Removal of the volatile extrusion aid should be performed at a rate slow enough to prevent blistering. With naphtha as the extrusion aid, less than 5 min. is required for small tubing; up to 20 min. for 2-in. tubing with a 60-mil wall.

The additional heating time required for sintering is approximately the same as that required for volatilization when the heat source is hot air. The use of infrared heat reduces this time.

As much as 40% shrinkage, most of which occurs in the machine direction, may be experienced. Changes in wall thickness perpendicular to the axis of the tubing are very small.

The time the tetrafluoroethylene should remain in the amorphous state at temperatures above 620° F. must be determined experimentally and depends partly on the degree of longitudinal orientation produced during extrusion. The major portion of this orientation must be destroyed so that the finished tubing will have adequate strength in the circumferential direction.

Tubing over about 1 in. in diameter tends to distort out of round during sintering and cooling. This can be minimized by suspending shaping bulbs from the end of the mandrel at a point just below the sintering zone. These bulbs should be smooth, round in cross-section, and ⅛ to 3/16 in. smaller than the inside diameter of the tubing.

For tubing on the order of 1 in. in diameter and larger, nitrogen should be flushed through the tubing via a suction system attached to the hollow mandrel to remove the extrusion aid vapors from the inside of the tubing.

Wire coating extrusion equipment

The equipment used for the extrusion of wire insulation from compounded tetrafluoroethylene resin (see Fig. 2, p. 725) consists of an extruder cylinder and ram, a die, a drying and sintering oven, and standard wire coating pay-off and wind-up machinery.

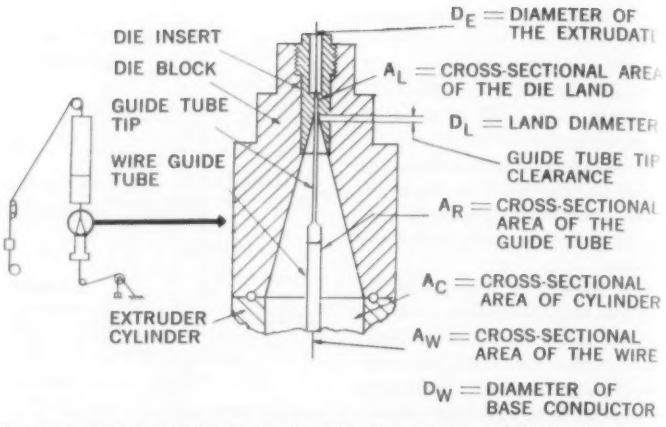

Fig. 3: Die for the extrusion of wire insulation from tetrafluoroethylene resin, used in set-up shown in Fig. 2, p. 725

The ram is driven by a screw-jack mechanism which enables a constant throughput of material regardless of extrusion pressure. This constant throughput of material is required to insure good caliper control of the extrudate. The extruder cylinder and ram should be able to withstand extrusion pressures as high as 30,000 p.s.i.

The die (see Fig. 3, above) is used to form the compounded preform into a strong fibrous coating with the desired wall thickness on the wire. The variables affecting the die performance are as follows:

1) The degree of included angle of the die cone; 2) the diameter of the die land; 3) the length of the die land; and 4) the temperature of the die during the extrusion process.

The included angle of the die cone affects the extrusion pressure and the smoothness of the extrudate. A 20° included angle die appears most suitable, particularly for thin-wall hook-up wire fabrication. Dies having an included angle of 30° are also used successfully for thicker wall insulations such as coaxial cable core.

The die land diameter is the basic determinant of the extrudate diameter. Generally, the die land diameter is about 6% less than the extrudate diameter. The extrudate diameter can be calculated to ± 1 mil by using equation (1) which was derived for the extrusion of Teflon 6 using No. 30 white oil or VM&P naphtha as an extrusion aid. The extrudate diameter is related to the volumetric displacement rate of the ram and the wire coating speed by equation (2).

$$\frac{D_E^2 - D_W^2}{D_p^2 - D_W^2} = 0.944 + 2.85\frac{X}{1-X} \qquad (1)$$

$$V_R = \frac{3\pi}{10^6}(D_E^2 - D_W^2)\,S_W \qquad (2)$$

where: D_E = extrudate diameter in mils; D_p = product diameter in mils; D_W = conductor diameter in mils; X= lubricant concentration in g./g. of lubricated tetrafluoroethylene; V_R = volumetric displacement rate of ram (cu. in./min.); and S_W = wire coating speed in ft./minute.

The length of the die land affects the surface smoothness of the extruded coating. In general, the longer the die land, the smoother the coating. The die land length is limited by shear imposed by the wire which causes the coating to tear when land length is excessive. In practice, die land lengths from ¼ to ½ in. have been found to produce an extrudate having a smooth surface and one that is free from tears.

The temperature of the die during extrusion should be maintained above 75° F. Die heating aids the drying operation by preheating the extrudate, which in-

creases the rate of diffusion of the lubricant to the coating surface where it can be vaporized.

The guide tube and tip provide a guide for the wire through the extruder cylinder to the entrance of the die land. The clearance between the die land entrance and the guide tube tip can be varied to control the length of wire exposed to the compounded polymer in the die.

Wire coating extrusion operation

The wire coating extrusion operation, similar to the tubing operation, is carried out on a batch basis. The preform of compounded tetrafluoroethylene is forced through an extrusion die onto the wire by a ram. The pressure required to extrude this stock is highly dependent on the reduction ratio which is a direct measure of the shear or deformation imposed on the tetrafluoroethylene particles.

In practice, successful fabrication is limited by the upper and lower extremes of reduction ratio. At reduction ratios of 2,000 to 3,000, fracture of the polymer may occur in the die, resulting in an extrudate sheared into discontinuous pieces. At reduction ratios around 100, the particles are not elongated sufficiently to be suitable for wire insulation. These limits also depend on the extrusion aid concentration and the insulation construction in question, and are therefore not specifically definable.

The clearance between the guide tube tip and the entrance to the die land is also an important factor in this process. If the clearance between the tip and the die land is properly set, the average velocity of the lubricated polymer in this area is the same as the wire speed. If the clearance is too large, the polymer speed is slower than the wire speed, which causes excessive shearing of the polymer particles in contact with the wire. This shearing action increases the wire tension enough to cause a wire failure and causes numerous coating flaws. Should the clearance be too small, the guide tube tip tends to plug the die, causing high extrusion pressures. This plugging action causes surging of the lubricated polymer around the wire, resulting in rough, discontinuous coatings.

Drying and sintering of wire insulation

The extrudate of tetrafluoroethylene leaving the extrusion die contains about 19% by weight or 40% by volume of naphtha. In the drying oven this extrusion aid diffuses to the surface of the coating and is vaporized. It is important that all the vaporization of the extrusion aid take place on the coating surface to prevent cracks. The rate of diffusion and vaporization is controlled by the drying oven temperature. Drying oven temperatures generally used are about 300° F. at the entrance up to 575° F. at the exit. During drying operations the oven should be exhausted sufficiently to keep the naphtha fume concentration below 0.9 percent.

The coating leaving the drying oven is very porous. The forces of coalescence in sintering are strong enough to eliminate these voids with a reduction in the coating diameter. The coating must reach a temperature of at least 621° F. for a few seconds to effect this sintering. While the tetrafluoroethylene is in the gel state (621° F.) it should not be submitted to stresses. To enable the coating to be sintered properly, the sintering oven is maintained at 700 to 750° F. The sintering oven should be equipped with an exhaust system to remove possible trace quantities of toxic fumes given off during sintering or from coated wire left inadvertently in the hot ovens.

Adequate ventilation is a recommended precaution against the inhalation of small amounts of gaseous decomposition products encountered when processing Teflon tetrafluoroethylene resins at temperatures above 400° F. (204° C.). The use of proper ventilation is so effective that there are no known cases of ill effects where suitable precaution has been exercised.

EXTRUSION OF POLYVINYL CHLORIDE

BY ALLAN G. FOLSOM*

The tabulation of equipment design data for the extrusion of vinyls (See Table I, p. 728, and Table II, p. 729), either plasticized or unplasticized, is not easily accomplished. The complexities of vinyl formulation and the variability in form of the feed material require many mutations in extrusion equipment.

The formulations vary from the hard brittle 98% PVC resin type to a compound having a viscosity little higher than that of a paste. The vinyls are fed to extruders in the form of powder, diced or granulated compound, or in the form of a hot strip continuously supplied by roll mills. In extruding polyvinyl chloride, it should be remembered that no single extruder design can be optimum for all vinyl materials or applications.

Plasticized vinyl

Equipment: Plasticized polyvinyl chloride is successfully extruded on single- or twin-screw extruders. It should be pointed out here that, in normal production, slightly higher physical properties are developed in a compound that is Banbury mixed and milled prior to extrusion. The twin-screw machine is finding increased use in the extrusion of dry-blend material since its high-shearing action compensates for the compound-working lost in by-passing the Banbury mixing and milling operations.

A single-screw machine for the extrusion of dry-blend requires higher heat and frictional input than would be necessary in a machine for extruding diced vinyl

compound. A length-to-diameter ratio of 18 or 20:1 is recommended with a 3.5 to 4.5:1 compression ratio. The flight depth at the head end of the screw and clearance throughout should be much less than those used for diced compounds to insure adequate fusion. A finer screen pack than is used for diced material is generally required for dry-blend extrusion.

Hot-strip feeding is frequently utilized in the production of plasticized vinyl tubing or garden hose. Using a low compression ratio screw at 70 or 80 r.p.m. with strip feed results in a 50 to 100% increase in rate over an extruder fed with diced material.

monofilament can be extruded either in the horizontal plane or through a vertical head. The more rigid the compound, the more applicable it is for horizontal extrusion. When extruded horizontally, the strands from the multiple opening die are normally carried to a spreader comb located in the water bath. A softer compound is more readily forced through a 90° head and dropped vertically into the cold water cooling bath.

Film and sheeting: Vinyl film or sheeting can be extruded either through a flat film die or a circular blown-film die. In practice, it is common to use a flat sheet die for materials over 5 mils thick. The fish-tail-type design gives better service with plasticized PVC as it does not contain contours or hot spots common to the manifold-type die. Film less than 5 mils thick is usually produced by extrusion through a circular die to form a thin-wall tube. This tube is inflated with compressed air and allowed to stretch while hot to the desired film thickness. The air-cooled sheet passes through

a set of pinch rolls which maintain the desired amount of air pressure within the tube.

Wire coating: The coating of wire with plasticized PVC is generally accomplished with an adapter known as a cross-head. The operation is somewhat similar to that of making tubes, but in place of a solid mandrel, a hollow cone is used through which passes a heated wire. This hollow cone or guider usually has replaceable tips to accommodate various sizes of wire. The die bushing or orifice is fitted into a die holder which can be adjusted during operation by means of set screws to insure a concentric fitting around the wire. Some designs are so accurately fitted and so well streamlined that they are self-centering.

Die design for PVC

Profile die design for plasticized polyvinyl chloride is dependent on the length of the extrusion run and the complexity of the extruded shape. For the extrusion of complex profiles used in gasketing, it frequently is more profitable to use a rectangular or plate die with minimum streamlining, and clean it often, rather than to produce the costly streamlined die which would reduce down time. For garden hose, however, long runs and simple shape make the use of streamlined tube dies most profitable. A profile plate die for vinyl should have approximately 1 in. of land length for each ¼ in. of cross-sectional thickness. High output of a small cross-section requires a proportional increase in land length. The approach angle for such dies is normally 30 to 45°. Shape and cross-section dimension of dies must be established on a trial-and-error basis but an initial design can be established by allowing for a 20% draw-down on the major dimension and a 5% draw-down in the minor direction. Dies built for long continuous service should always be of stainless steel or chrome-plated.

A tubing die consists of two parts: an adjustable, replaceable outer die bushing, and a fixed but replaceable pin or mandrel. The mandrel controls the inside diameter of the tube and is held in the die by a spider arrangement; the bushing governing the outside diameter of the tube is concentrically adjustable with set screws to insure uniformity of wall thickness.

Purging routine: Removal of the head, lowering of machine temperatures (25°), and the introduction of additional stock result in satisfactory purging. The die must be cleaned out manually.

Unplasticized vinyl

Equipment: As with plasticized vinyl, UPVC is commercially extruded on both twin-screw and single-screw machines. Most commercial extrusion, whether on twin- or single-screw machines, is accomplished by extrusion from granules. Extrusion from preblended powder is an extremely critical process in which the optimum physical properties of the compound may or may not be developed. The double heat history resulting from Banbury mixing and milling prior to extrusion results in high-impact strength in the extruded product.

Much European PVC pipe production is the result of hot strip feeding. In the U.S.A. at the present time, this type of processing has not advanced beyond a speculative interest.

Die design for UPVC

Dies to be used for the extrusion of UPVC should be designed with the utmost possible streamlining. Rectangular or plate dies should not be used. It is preferable that the die be machined from a stainless steel with a high nickel content. Poor machinability, however, makes the use of a 18-8 type more common. An acceptable alternative would be a die machined from SAE 1020 hardened, and plated with chromium to a thickness of 0.0005 inch.

True rigid vinyl materials do not lend themselves to extrusion through offset or cross-head dies. The extrusion of monofilament must therefore be accomplished through use of a horizontal extrusion technique. Rigid PVC film may be extruded using a flat fish-tail design die. Such a film, when oriented biaxially, produces a tough, versatile sheet.

Pipe and tubing is the most common application for UPVC. Available in diameters from ¼ to 12 in., PVC pipe is produced with dimensions similar to those of iron pipe.

Purging routine: Same as for plasticized vinyl.

EXTRUSION OF A-B-S POLYMER BLEND

BY E. J. TRUNK*

Acrylonitrile-butadiene-styrene polymer blend can be easily extruded in conventional equipment. Its relatively high heat stability contributes to this ease of extrusion.

Momentary extruder shutdowns of up to 1½ hr. for minor repairs are possible without lowering cylinder temperatures. Purging of material at the end of a run is unnecessary. The usual procedure for shutdown at the end of a run is to cut off the feed hopper and permit the extruder to run until flow of material from the die stops. Since the screw will clean itself, screw removal is unnecessary.

Material handling

Prior to extrusion, the material must be dried. Drying is most effectively carried out in hopper

* Naugatuck Chemical, Div., United States Rubber Co., 203 Elm St., Naugatuck, Conn.

driers or in open trays with the depth of the granules no greater than 1 inch. Circulating-air or forced-draft systems should be used. Drying time is a function of air temperature and will vary from 4 to 6 hr. at 170° F. to 1 hr. at 220° F. Material may be fed hot to the extruder if a relatively uniform temperature can be maintained. In hopper feed drying systems, it is recommended that the air fed to the hopper should range between temperatures of 180 and 200° F.

Caution must be used to prevent bridging of material because of overheating. The hopper capacity should be 4 to 5 times the extruder hourly extrusion rate. The use of a vented extruder will not completely eliminate the need for material drying.

Equipment

Extruders and screws: Extruder and screws should be of standard material construction as supplied by the manufacturer. The acrylonitrile-butadiene-styrene polymer blend can be extruded with almost any type of extruder screw, but for the most efficient operation, constant flighted screws having a compression ratio of 3 or 4:1 are recommended. Certain blends, e.g., Kralastic B-3 materials[2], require slightly more working, and therefore, are more critical as to choice of screw. Consequently, such screws as the shallow-flighted 4:1 compression, the mixing-type (Dulmage) or the metering-type (nylon) are best for these materials and will give optimum outputs of finished product.

Dies and pins: In general, the straight-through die head is recommended for extrusion of this material. Offset and crosshead dies have been used in the extrusion of pipe; however, with such dies the production of quality pipe is slightly more difficult. Dies and pins should be highly-polished hardened steel and chrome-plated for best performance. The chrome dies generally permit longer extrusion runs between teardowns.

Die land length should be about 16 to 20 times pipe wall thickness. However, a good rule of thumb is to use "square" dies, i.e., land length equal to diameter. The I.D. of the die should be 10 to 15% larger than required pipe O.D. to permit draw-down. This, however, does not always hold when O.D. or I.D. sizing mandrels are utilized. In such cases, die I.D. and finish pipe O.D. remain approximately equal.

[2] Trademark of United States Rubber Co.

TABLE I: Throughputs in various extruders

Screw diameter	*Throughput*
in.	*lb./hr. (ppH)*
1½	35-45
2½	70-100
3½	130-185
4½	175-250

Pin O.D. for use with the 10 to 15% oversize dies is determined by simply subtracting twice the finished pipe wall thickness from the die I.D. For O.D. or I.D. sizing mandrels, the die-pin clearance should be approximately 15 to 25% greater than the pipe wall thickness. Restricted-flow type pins such as are used with the cellulosics also perform well with the acrylonitrile-butadiene-styrene materials.

Screens: In general, screens are not needed to build up back pressure with the material but one or two 20- or 40-mesh screens are recommended to homogenize the material and to prevent cold slugs from passing through the extrusion die.

Pipe sizing: Several methods of pipe sizing are used. Among these, probably the three most popular setups are: 1) first-stage multiple air rings with second-stage water cooling; 2) multiple sizing ring with cascade and/or immersion water cooling; and 3) I.D. water-cooled mandrel with one or two O.D. sizing rings followed by cascade or immersion cooling.

Water bath: The water bath should have a continuous cool water supply and should be 10 to 14 in. wide by 10 to 20 ft. or more long, the length depending on anticipated extrusion rates. The tank should be equipped with adjustable contoured rollers, spaced at 10- to 14-in. intervals to hold the pipe down in the water. On pipe larger than 4 to 5 in. in diameter, it is recommended that water be cascaded over the pipe because of difficulty in keeping larger diameter pipe submerged and the possibility of collapsing the extrusion.

Takeaway or capstan: Unless there is an even, steady pull on the extruded pipe as it leaves the die and is pulled through the sizer, a good product is impossible. For this reason, the takeaway or capstan is probably one of the most important pieces of auxiliary equipment used in the extrusion of pipe.

A capstan, consisting of 4 to 6 drive rollers of contoured rubber, with weighted or spring-loaded idler or driven rollers and a good nonfluctuating adjustable speed drive, is essential. The new rubber timer belt drives are also excellent pulloffs. Drive motors of ½ to 1 hp, or greater are necessary, depending on the size of the pipe.

Operating temperature

Temperature control for acrylonitrile-butadiene-styrene is not quite as critical as for other materials. The appearance and physical properties of the extruded product are the best criteria for determining proper operating conditions. These will vary considerably from one machine to another. Material temperature at the exit of the die is the prime consideration, and this temperature should run from 400 to 440° F. when checked with a needle pyrometer. A typical set of operating conditions would be as follows:

Barrel temperature (feed-end)	350 to 370°
Barrel temperature (center)	370 to 400°
Barrel temperature (die-end)	400 to 425°
Die temperature	400 to 450°

Cooling water is generally not required on the screw.

Production rate

Listed in Table I, above, are the approximate throughputs of Kralastic in various-sized extruders.

Rates for various wall thicknesses on a given size pipe can be easily determined as rates are al-

most a direct function of thickness ratios. However, because of screw reflections or undulated surfaces, which sometimes occur on pipe surface when extruded at maximum rates, a slower production rate is used in order to keep scrap at a minimum.

EXTRUSION OF POLYETHYLENE

Polyethylene can be readily extruded into a wide variety of shapes—pipe, monofilaments, thin films, or other profiles. The material can also be extruded as a coating over wire or onto paper and other substances, where its electrical and mechanical properties are of value. Extrusion conditions for each of these shapes and for coatings vary widely and are summarized in Table I, p. 733.

Extrusion of pipe

Considerable interest and discussion has arisen regarding the various systems for extruding polyethylene pipe. Because of the great diversity of equipment being used in the field for the extrusion of polyethylene pipe and tubing, recommendations must necessarily be general.

Die design: Tubular dies with long parallel lands are generally used for the extrusion of polyethylene pipe. In general, the longer the land, the better the pipe surface, but, in practice, the best arrangement will be dictated by proper balance between factors of compound temperature and production rate. A general working rule for design of dies intended for the extrusion of heavy-wall tubing normally considered as pipe is as follows:

Die size	20% greater than pipe aim OD
Pin size	22% greater than pipe aim OD
Die land	Equal to the die OD

Maximum streamlining in all components is naturally desirable throughout.

Temperature control: In order to extrude polyethylene pipe satisfactorily, good temperature control must be maintained. The temperature of the polyethylene must be sufficiently high as it comes from the extruder to obtain smooth, uniform pipe walls, but not so high as to cause collapse of the extruded section before cooling can take place. This exact point can generally be reached on any given extruder only after a certain number of trials. Compound temperatures below 260° F. should generally be avoided so that good welding or fusing of any pipe seams, produced by the flow of plastic around obstructions in the head or die in the course of extrusion, will be obtained. Compound temperatures which are above 280° F. may make it extremely difficult to produce round, uniform pipe and operations are likely to be hampered by sticking at the sizing plate or by collapse of the pipe as it enters the cooling bath.

Auxiliary equipment: A typical polyethylene pipe extrusion assembly consists of an extruder followed by appropriate pipe sizing facilities, pulling device, and coiling or cut-off equipment. Any mechanical device capable of exerting the required tension on the pipe as it is extruded may be used. Finished pipe should not be deformed or defaced by this.

Pipe sizing: Several pipe sizing techniques have been employed in the field with favorable results. One technique involves drawing the extruded pipe through a cooling sleeve. Another technique employs an internally cooled, tapered mandrel, over which the extruded pipe is drawn to obtain the desired dimensions. A third method involves the use of sizing plates positioned in a water-cooling trough. In this latter technique, by properly adjusting the distance between the two sizing plates used and by employing the correct sizing hole, the diameter of the extruded pipe can be controlled. Final reduction to size will occur through cooling between the second sizing plate and the pulling device. Additional sizing plates can be used where the linear pipe speed is high and longer cooling time is necessary to cool the pipe to the point that shape will be maintained. When using this technique, the I.D. of the pipe can be adjusted to give the desired wall thickness by varying the speed of the pulling device with relation to the rate of extrusion.

Extrusion of monofilaments

Extruder screw: Conventional screw designs have proven satisfactory for polyethylene monofilament extrusion. Screw temperature is a controlling factor in product uniformity and output rate. A bleed of atmospheric steam through the screw or a neutral screw will generally result in the highest output rates.

Die design: The die orifice should be approximately equivalent to the diameter of the monofilament before orienting—never larger in diameter. If the orifices are larger, the monofilaments must be hot-stretched at the die to attain the desired size, in which case they may lack sufficient strength to be cold-stretched in the subsequent orientation operation and frequent breaks may occur.

While the same dies may be used interchangeably for polyethylene and styrene resins, since the recommended stretch for polyethylene (600%) is less than that for the styrene resins (800%), the size of the oriented fibers extruded from the same orifice will be different. Typical die sizes for producing fibers oriented 600% are as follows:

Size of orifice	*Oriented monofilament size*
in.	*in.*
0.070	0.027
0.060	0.023
0.050	0.019
0.040	0.015
0.030	0.012
0.020	0.008

Stretching and orienting: In a typical stretching and annealing process, the polyethylene monofilaments are extruded vertically into a quenching bath of room-temperature water. A travel of 50 to 60 in. is sufficient to achieve cooling. A freely rotating or

driven smooth-face roll at the bottom of the bath will improve the roundness of the fibers. A take-up godet, or driven snubber rolls, may be used to draw the extruded fibers from the die at a uniform rate. It is not necessary to heat these rolls since polyethylene is inherently flexible.

Stretching of the polyethylene monofilament is accomplished by a stretching godet operated at seven times the linear speed of the size control system. Stretching and orientation is carried out in room temperature air. For improved tensile strength, a 575 to 600% stretch is recommended. For maximum tensile strength, the monofilament should be annealed in the water bath under constant tension at 85 to 95° C.

Improved high-temperature shrinkage can be obtained at a sacrifice in tensile strength by passing the monofilament through two annealing water baths at 85 to 95° C. In this procedure, tension should be relaxed approximately 22% in each bath.

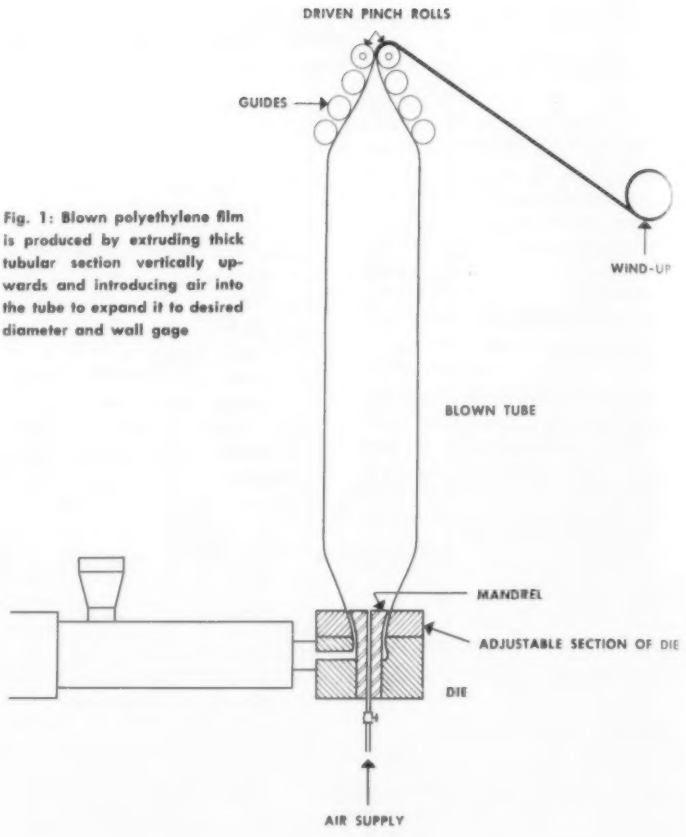

Fig. 1: Blown polyethylene film is produced by extruding thick tubular section vertically upwards and introducing air into the tube to expand it to desired diameter and wall gage

Film extrusion

There are two major polyethylene film extrusion processes for polyethylene resin:

a) Flat film extrusion.

b) Blown film extrusion (expanded tubing).

Flat film: In flat film extrusion, the extruder delivers molten polymer to the die, and from there the film passes into the quench bath, where it is cooled. The cooled sheet passes through a set of pinch rolls, is trimmed, and wound up.

The extruder barrel is heated to between 425 and 500° F., the higher temperature being used for higher extrusion rates.

The die consists of a polished manifold, slotted along its length, and may be equipped to receive molten resin through either of its ends or through an orifice located midway along its length. The manifold should be, where possible, of one-piece construction with a bore that has been precision-drilled, reamed, and given a high polish. The slot should be carefully milled and polished.

The die face can be either 90 or 180°. Flat-surfaced dies which have jaw movement in only one plane can be more easily adjusted by the operator. The die jaw lands, over which the polyethylene resin flows, are about 1/16-in. long and must be carefully polished and maintained. It is desirable to design the die in such a way that die jaws can be adjusted while the machine is running. This may be done with alternate push and pull bolts along the length of the die. The die jaws are set initially to give a uniform opening across the width. This opening for thin film should be between 0.012 and 0.030 inch. If the width of the sheet is to be varied, a short section of 1/8-in. brass rod may be inserted at each end of the die, just above the jaws, in such a way that it can be moved in or out. The rod, forced against the die jaws by the pressure of resins, acts as a check valve.

As the molten film of polyethylene resin leaves the die opening, it is drawn down into a quench tank. The water level may be between 1 and 5 in. below the die face. It is convenient to have the tank height adjustable so that it may be lowered while changing or cleaning dies. The quench water should be fed to the tank with a minimum of turbulence. To minimize surface ripples and maintain a constant level, the water should overflow the sides of the tank through weirs. In order to obtain uniform film properties, it is important that the quench bath be maintained at a constant temperature.

The film, after it leaves the die, is drawn into the quench tank, around a polished roller or stationary guide shoe, and out of the tank by means of a pair of pinch-rolls. The speed of these pinch-rolls governs the draw-down of the molten film as it travels through the air gap between the die and the quench tank, and determines the final caliper of the film.

The trimming operation is per-

formed with either a stationary or a rotary-blade unit. Trimming is necessary to remove the edge material which is thicker than the rest of the film. Usually ¼ to ½ in. is removed from each edge by this operation.

After trimming, the film is drawn through a second pair of pull-off rolls which feed it to the final takeup roll. This roll is usually axially driven and best roll formation has been obtained from a constant torque system of winding.

Blown film: In this method, the stock is extruded from the die as a comparatively thick tubular section which is expanded by air pressure, while still molten, to the desired size and thickness. The tubing is usually extruded vertically upward though it may also be extruded downward or horizontally. Air is maintained in the tube by the closed die at one end and the motor-driven squeeze rolls at the other. From the squeeze rolls it goes to a wind-up machine.

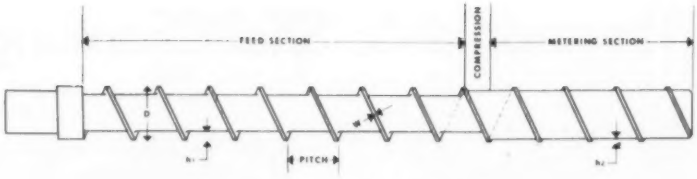
It is of the utmost importance that caliper be uniform to insure wrinkle-free film and even wind-up of rolls. The internal air pressure, extruder output, die adjustment, take-off speed, and temperature are factors which also affect caliper.

In the extruder used for blown tubing, barrel temperatures are lower than those used for flat film extrusion. Temperatures between 300 and 375° F. are typical. The extruder melts and conveys the melted resin to the die.

The die may be bottom or side fed, but in either case the polyethylene flows around a mandrel which forms it into a tube. The die annulus is commonly 0.015 to 0.025 in. and is usually adjusted as soon as possible after start-up.

As the polyethylene tube issues from the die, it is drawn manually to the pinch rolls which take it off at a uniform rate. Air is then admitted slowly through the center of the mandrel to expand the tube to the desired diameter. It is then shut off, leaving a locked volume of air in the tube.

Extrusion coating



The extrusion coating process consists essentially of these three steps: Film is extruded at high temperature. While in a molten state it is drawn through the nip of two rolls where it comes in contact with the substrata. Pressure is applied by the rolls to effect lamination. One roll is a water-cooled chill roll which solidifies the polyethylene; the other is a rubber pressure roll.

The process requires an electrically-heated machine, since the resin must be heated to a temperature of 600° F. The extruder die should be located so that the film meets the substrata at the nip of the rolls or slightly to the rubber roll side. If it touches the cooled roll first, adhesion will be poor.

The pressure roll is made of a heat-resistant rubber cured to a Durometer hardness of 60. The pressure, though not critical, should be in the range of 60 lb./in. along the surface of contact.

The chill roll consists of a spirally-cored jacket cooled with water so that the surface temperature does not exceed 150° F. The chill roll is driven by a variable-speed motor which draws the film to the desired thickness.

It is necessary to trim the edge of the coated material to remove the bead formed on each edge.

Fig. 2: Metering-type rapid compression screw for extruding polyethylene

Wire coating

Since polyethylene resin is an outstanding dielectric with excellent physical properties, it is used as an insulating jacket in many types of wire construction. In a typical coating operation, wire is paid off from a device which maintains constant tension. Preheating of the wire improves adhesion of the coating and helps to remove any residual oil or drawing die lubricant which may be present. The wire may be heated by either of two methods: by gas burners or by resistance heating.

From the preheater, the wire passes into the die and guider mounted in a cross-head. The pressure exerted by the screw forces the polyethylene resin over the guider and out of the die.

At the same time, wire passes through the guider and emerges coated with a sheath of polyethylene. Wall thicknesses from less than 0.010 in. to greater than 0.500 in. may be applied. The rate at which wire is coated is dependent mainly upon the wall thickness to be applied. Insulations have been extruded on wire at a rate of greater than 2000 ft./min. and on cables about 2 in. in diameter at a rate of 30 ft./minute.

Purging routine

A highly-filled vinyl compound should be used to purge out the polyethylene. Machine should be cooled to approximately 320° F., before purge is begun.

Thermoplastic Sheet Forming

BY ROBERT L. BUTZKO* and E. BOWMAN STRATTON, JR.*

Vacuum forming accounts for the production of the majority of the thousands of jobs now being turned out by sheet forming. In this process, heating and forming take place in one machine, which may be manually or automatically controlled. After the sheet is heated, a vacuum removes the air from between it and a mold, and atmospheric pressure forces the softened sheet against the mold.

The vacuum system of such machines consists of a vacuum pump and reservoir tank. The pumps are of the high-capacity type rather than the high-vacuum type, and deliver a vacuum of about 28 in. of mercury. Both rotary and piston type are used with equal success. In the higher capacities, water-cooled pumps are required. The tanks are of large capacities and, together with the pump, are engineered to provide adequate recovery rate for a particular size of machine. When several machines are installed in one plant, a central vacuum system is usually used, piped to the individual machines. This reduces the cost of the individual machines and saves space.

The development of accurately controllable high-temperature heaters has been a major factor in the rapid growth of vacuum forming. Methods of heating by steam, hot water, hot oil, and infra-red lamps have been used but have been generally discarded since most of these methods of heating are too slow, or result in spotty heating and consequent poor-quality formed pieces.

Present commercial machines employ heaters using electrical resistance wire in some form. Heaters have been made with Nichrome resistance wire encased in fibrous glass tubing and cloth to produce a mat-type heater, which provides uniform heat, but cannot exceed 700 to 800° F. since the glass will crystallize at higher temperatures. These heaters, while satisfactory in the past, cannot compete in the high production requirements of the present day; because of the comparatively low temperatures available, heating cycles are too slow. For example, 0.100-in. thick high-impact styrene sheet requires over 100 sec. to heat using a mat-type heater; present-day heaters will accomplish the same result in approximately 40 seconds.

Many new machines employ heaters using enclosed tubular-type elements. These completely sealed units have exceedingly long life since the elements are not exposed to humidity, dust, mechanical abrasion, or fumes from the plastics sheets being heated. The design of the heater is not uniform, but is worked out to compensate for heater travel, cold-air flow, and edge-cooling effect. Heaters are constructed with stainless steel throughout for resistance to corrosion, and are heavily insulated to prevent heat loss to the working area. Insulation below the heater in the nonheating cycle makes the machines comfortable to operate and, at the same time reduces the electrical drain.

The application of controls to the basic machines results in an approach to automation. In general-purpose machines, the variables of heating, cooling, and forming require constant control and the design of the control system is of the sequence type.

In general, compressed air is used to motivate most of the actions in this type of equipment. This is practical because air devices provide the long stroke and variable speeds necessary for this process. Most modern machines provide both automatic and manual controls. The setup and determination of the factors of forming are tested manually. Then, after the process has been smoothed out, the machines are switched to automatic control and production begins without further manual operation.

While it has been stressed in many articles on sheet forming that pressures in vacuum forming are relatively low (14 p.s.i. or less), it must not be overlooked that the *total* pressure exerted on a large mold can run to high values. Thus, for example, when using a mold 48 by 72 in., a pressure of 48,000 lb. is imposed on the sheet and also on the table to which the mold is gasketed. As the vacuum is pulled, atmospheric pressure tends to force the sheet downward against the mold and also, in effect, to force the table upward. Machine tables must be adequately heavy and strong to withstand this sudden impact; other structural parts of the machines must be strong in proportion. Present-day vacuum forming machines are of all-steel construction and embody the latest in welded and machined structural elements.

The following discussion treats with machines that form by straight vacuum or drape or a combination thereof or which are based on some variation of pressure or mechanical forming. There have been some recent developments in the field. Two new techniques have aroused interest —plug-assist forming, in which a plug, which approximates the shape of the cavity, forces the sheet down into the mold, and air-slip forming, in which the male mold is carried upwards toward the clamped sheet compressing the air between the top of the mold and the sheet. Toward the end of the stroke, the male mold catches up with the bubble thus formed, the trapped air is evacuated, and the sheet is pulled down against the mold. Another type of machine under development is the "rotary" type which is based on the idea of a large turn-table

* Auto-Vac Co., 1984 State St. Ext., Bridgeport, Conn.

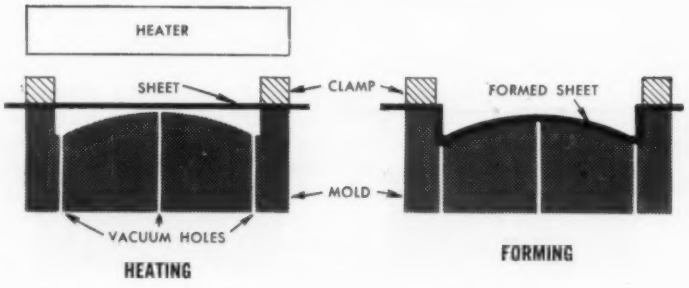
References were prepared by the editors.

revolving in front of the operator. Stopping at each 120 degrees of travel places the clamping frame in front of the operator who can then unload and reload.

Straight vacuum machines: One of the easiest types of forming at the present time is the use of vacuum alone to pull a heated sheet into or over a mold. This type of forming may be performed on a special machine for straight vacuum only, or may be performed on one of the combination drape and straight vacuum machines that are on the market.

In a straight vacuum machine, the sheet clamp is usually attached to the mold or mold box, and is operated manually. In the combination machines, clamping is automatic. In the latter, the operator places the plastic sheet atop the mold and presses the starting buttons. The machine takes over, clamping the sheet, sending the heater over the sheet, heating for a timed interval, and opening the vacuum valve. After a timed cooling period, the vacuum is shut off, the clamp opens, and the formed piece is removed. The operator then inserts another sheet for the next cycle. With this type of operation, one operator may run two machines or may do other work such as trimming the formed parts. With the heater directly over the sheet and mold, split-second control of the heating cycle allows the vacuum valve to snap open when the exact molding temperature is reached.

Products made by this process are of the low-profile type, since the deeper the cavity, the thinner will be the plastic form. A rule of thumb generally used is that straight vacuum is used where the diameter of any opening is no less than twice the depth.



Vacuum forming plastic sheets decorated by silk screening or printing has developed into big business. By coloring flat sheets in a distorted pattern which is registered in the clamping frame, pieces with highly accurate decorations may be produced inexpensively. Rigid vinyl is used for most of these products although styrene, acetate, butyrate, and acrylic are also used.

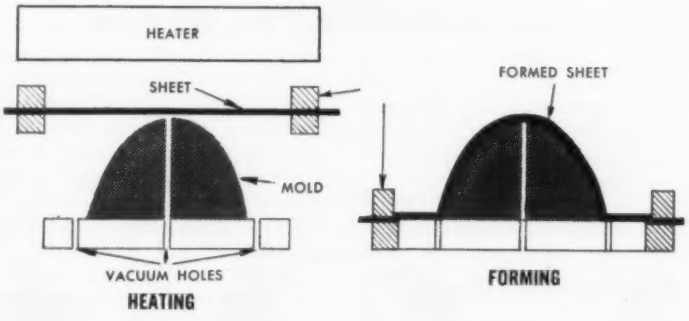
Straight vacuum forming over male mold: A variation of straight vacuum forming is vacuum forming on a male form placed in a cavity. This type of forming places the thickest part of the plastic part on the top, resulting in a stronger part. However, much more waste occurs since the plastic must be drawn down the sides of the female portion sufficiently far to prevent excess thinning at the base of the male plug. This type of forming was used extensively before the development of equipment for drape forming, described below. Some products with low profiles are still molded economically by means of this method.

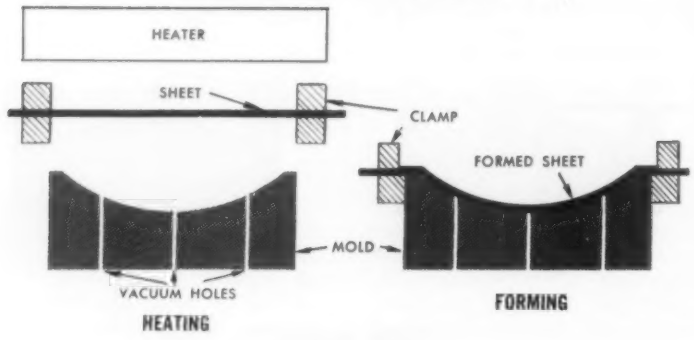
In the molding of one type of three-dimensional map by this process, vacuum is applied to the combination mold before heat is applied to the sheet. As the sheet softens, the vacuum drapes the sheet over the male mold and down around the sides. When the sheet is fully formed, the heat is removed. Proponents of this type of molding claim that greater accuracy of registration is possible since the sheet is immediately locked on the projections of the male mold.

Drape forming over male mold: By the drape process, plastic products can be formed with

VACUUM FORMING OVER MALE MOLD

DRAPE FORMING





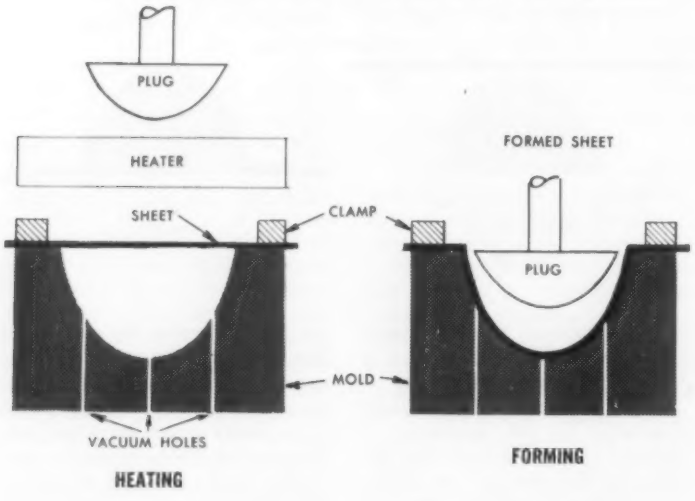


TABLE I: Heat cycle and forming temperatures

Material	*Gage*	*Heater temperature*	*Distance between heater and plastic*	*Temperature cycle of plastic sheet*

DRAPE FORMING INTO FEMALE MOLD

VACUUM FORMING INTO FEMALE MOLD WITH HELPER

thick wall sections without extreme waste. In low-profile forms, parts may be formed either by straight vacuum or by the drape process; however, a better product can be formed from a thinner sheet by the drape process. In the drape process the plastic sheet is draped or pulled over the male form until the level of the sheet is down to the lowest height of the mold. The sheet is then sealed at the edges of the mold and the vacuum applied, pulling the sheet to the contours of the mold. Parts may have female sections within the male form, thus making possible the successful forming of many complicated shapes.

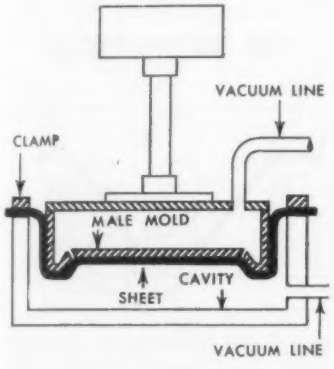
Forming of precolored sheets can be accomplished, but very close control of prestretching is required. The use of temperature-controlled molds eases this process since the slip of the plastic sheet is governed by mold temperature.

Refrigerator parts are among the high-production items formed by the drape process. The inner side of a door is a prime example. Formerly these doors were injection molded, usually on 200- or 300-oz. injection machines. Mold cost ran approximately $25,000 each and required from 14 to 20 weeks to obtain. Vacuum molds cost from $1200 to $2000 each and cutting dies from $2000 to $4000. These molds and dies may be obtained in about 6 weeks. With such low tooling costs, vacuum forming permits design changes to be made every year, whereas most injection molds are expected to last three years to amortize the tooling.

Drawing to extreme depths is a recent development of the drape process. Rigid vinyl is us successfully to form parts which the depth is 1½ times th diameter, but normal draws the drape process seldom exce a 1 to 1 ratio of depth to diamete

Drape molding into femal cavity: A variation of the drap process is draping into a femal cavity. Some materials such a flexible vinyl or some of the heavy plastics will droop consid erably upon heating and lock upon the mold, causing uneven products. By elevating the sheet in the heating process, the plastic is held far enough away from the mold so that the plastic sheet will not touch it. After heating, the sheet is draped in the conventional manner and the vacuum forms the part.

Automatic roll - feed drape forming: On one machine, the operation is completely automatic, requiring no operator in constant attendance. As many as 50,000 small parts per hr. are possible and such jobs can run 24 hr. per day without interruption. Unlike hand-fed operations in which slight variations of cycle require slight adjustments during the day, the completely automatic vacuum forming machine will run continuously without cycle variation.



Temperature-controlled molds are a must. They are heated to the required temperature before the first cycle. Any material now on the market may be used in any thickness which can be rolled without a permanent set. The usual thicknesses are from 0.005 to 0.040 inch. The average roll from 12 to 15 in. in diameter weighs from 100 to 150 pounds. With this equipment, the material, on a roll at one side of the machine, is drawn over the mold where the clamping, heat, drape, and vacuum are applied automatically. At the end of the cooling cycle, the material is automatically unclamped and indexed forward.

An average thin-walled package part may be run 3 cycles per min. in a multi-cavity mold. Since the finished parts are still in web form as they leave the machine, they may be fed directly into an automatic cutter or directly into loading equipment.

Forming into a female mold

With helper: In order to reduce the thinning at the bottom of a part drawn into a female mold, a male plug may be used. In this case, after the plastic sheet is heated in place over the female mold, the plug is pushed downward against the sheet, drawing material from the sides into the bottom of the mold. Then, when the vacuum is applied, the bottom of the sheet has only a short distance to travel and does not thin out as much as with straight vacuum. This process has a disadvantage in that the plug will leave a mark-off on the sheet. The design of the plug is very important since just the right amount of plastic must be forced down to prevent thin spots from showing up in the side walls of the formed part.

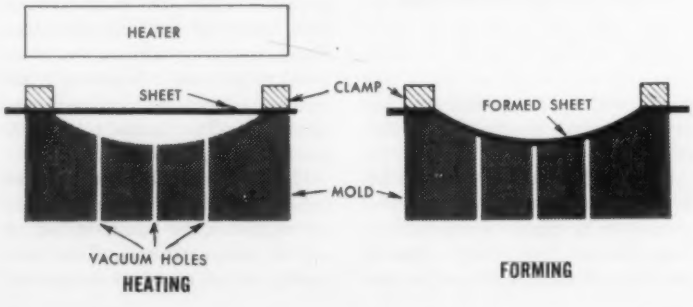
VACUUM SNAP-BACK FORMING

Extrusion vacuum forming: One of the most economical processes is vacuum forming the hot plastic sheet as it emerges from the rolls or die of a sheet-extruder setup. Proponents of this type of forming emphasize that all scrap can be reground and fed back into the hopper of the extrusion machine. Utilizing the heat already in the sheet, the forming in some cases is done directly as the sheet is extruded. In other cases it is necessary to have additional heat, since the sheet cools rapidly as it leaves the extruder.

In one type of forming, the sheet emerges on a moving belt and the mold is manually dropped on it and travels with the sheet and belt. After the mold has made contact with the sheet, the vacuum is turned on and draws the plastic into the mold. After the mold has traveled with the sheet until the part is cooled sufficiently, the vacuum is turned off and the mold lifted off and reset on the next section of the plastic sheet.

In a later type of machine, the mold is lifted and indexed automatically. In most extrusion-vacuum forming operations the molds are applied to the top of the sheet.

Snap-back forming: Another variation of vacuum forming is snap-back forming in which the sheet plastic is clamped on top of a vacuum box and heated. When the sheet has reached the correct temperature, vacuum is applied to the vacuum box, the sheet is pulled down to a predetermined depth, and a male plug, lowered into the cavity, clamps air tight on the vacuum box. The vacuum is now released from the box, and vacuum is applied to the male plug. The vacuum pulling through the tiny holes in the plug snaps the sheet against the plug, forming it to the contours of the plug.

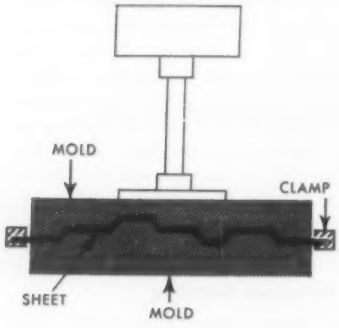


Some fabricators use vacuum in the box only. In this case, when the vacuum is released slowly, the natural tendency of most thermoplastics to return to their original flat shape causes the sheet to settle back against the plug. In this type of forming, however, reverse projections cannot be formed, but very little mark-off occurs and optical clarity of the material can be maintained. Snap-back forming is performed in an air press with an overhead piston and, as a general rule, the plastic is clamped in a frame and heated outside the press.

Free vacuum forming: For some types of forming where perfect optical clarity must be maintained, the plastic sheets can be molded into spherical shapes by free vacuum forming. Skylights, for example, are molded in this manner. The plastic sheet is clamped over a vacuum box and heated. When the sheet reaches the proper temperature, vacuum is applied, drawing the sheet into the box. When the part is of correct depth, the vacuum is reduced and held until the part cools. An electric eye circuit, actuated by the formed part when it reaches a predetermined depth, may be incorporated in the setup to control the vacuum.

Pressure forming

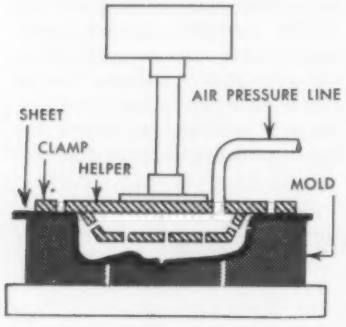
Since vacuum provides only about 14 p.s.i. pressure, better results may be obtained on some plastics and some products by using air pressure. Pressure up to 150 p.s.i. has been used. The equipment required is much heavier and consequently more expensive. Hydraulic presses with high ram speed and pressures from 50 to 200 tons are used and usually high-capacity hydraulic pumps are necessary. Most of the early flexible vinyl place mats were formed this way. Although production is usually slower than vacuum forming, better detail results from the higher pressure. Unlike vacuum forming, only metal molds may be used since the pressures will break down other materials. Care must be taken in making the molds since the pressure will force material



VACUUM FORMING INTO FEMALE MOLD

into any undercut and lock it in the mold.

Heating is accomplished by clamping the material in a frame and placing it in an oven. After heating to the proper temperature, the frame is placed in the hydraulic press and clamped shut. Air pressure then forms the



PRESSURE FORMING

part. Thinning is quite similar to that encountered in vacuum forming.

Pressure forming into female mold: In this type of forming, a hydraulic press is used to clamp the mold with the pressure plate and clamping must be adequate to resist the impact of the pressure. The metal female mold is

FORMING INTO FEMALE WITH HELPER AND AIR PRESSURE

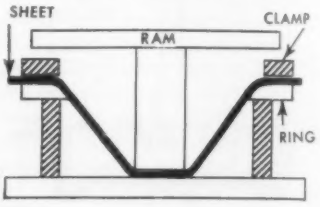
clamped to the press base and the pressure plate to the top of the press.

The plastic sheet is clamped in a frame and heated in an external heater to proper temperature. The clamp frame and plastic sheet are then transferred to the press and the press closed. Air pressure applied through holes in the pressure plate forces the plastic to the contours of the mold. Molds must be carefully polished since the pressure will pick up any defect in the mold and result in an unsatisfactory product.

Pressure forming into female mold with helper: To reduce the thinning that occurs in a female mold, a helper plug is sometimes mounted on the pressure plate. This has the effect of prestretching the plastic and drawing material from the side walls into the bottom of the cavity. The forming process is identical to that outlined for pressure forming into a female cavity. The design of the plug is important to pull the correct amount of plastic from the side walls.

Free blowing: Products requiring high optical clarity, such as aircraft canopies, may be formed by free blowing. In this type of forming, the plastic sheet is held in a clamp whose inside contour is the outline of the base of the finished product. The plastic sheet is heated and clamped over the top of a pressure box. Air pressure is then applied, blowing the plastic sheet to the required shape.

Many special jigs and adapters are necessary in this process to produce complicated shapes. Most of the success of this type of forming is due to the individual skill and techniques of the operator.



Mechanical forming

The oldest method of forming is by the use of straight mechanical actions without vacuum or air, and has many variations. Essentially, any sheet of correctly heated thermoplastic may be formed mechanically. Usually heavy mark-off occurs so the products must be those where this factor is not objectionable. Sheet metal equipment such as crank presses, benders, air presses, rollers, and creasers are used, as well as special tools such as curling equipment.

Male and female dies: Forming by male and female molds is accomplished by using molds of almost any material. The best molds are of matched metal but these are also the most expensive. In this process, the sheet plastic is heated in an oven or on a hot plate. When at the proper temperature, the sheet is placed over the female mold mounted in an air press. The male part of the die, which is attached to the ram of the press, is lowered, shaping the plastic between the two halves of the die. After a cooling period, the part is removed.

Plug and ring: A variation of male and female forming is the plug and ring, which has several different approaches. In this case, the plug and ring do not resemble the final part but the shape is drawn between the two. The plastic sheet, heated conventionally, is clamped over the ring and

PLUG AND RING FORMING

the plug is forced down into the sheet for a predetermined distance, forming the part.

Another method is to have a ring and a plug of smaller diameter, leaving just enough room for the plastic. The forming operation will produce a cup or shape with straight side walls.

A third variation, applied successfully for forming thin plastics sheets to shallow depths, uses a cold sheet. The male plug is heated and used on a slow-acting air or hydraulic press. The heat of the plug causes the plastic to stretch and form between the ring and plug.

Slip ring forming: In the previously described mechanical processes, the deeper parts stretch out considerably, resulting in thin side walls. In order to make a stronger part, a plug and ring setup may be used, in which the clamp exerts only low pressure. After heating conventionally, the plastic is held in this clamp and the plug pushed into the plastic

to draw the part. The loosely-held plastic sheet will slip under the clamp and draw into the side walls, producing a part with thicker walls than would be otherwise possible. Various types of clamping methods have been devised to control this slippage and to prevent the clamp from chilling the sheet.

In a variation of this type of forming, a grease-covered mold is used. The mold and plug must be heated so that the grease film is actually liquid. This reduces the mark-off which occurs from the slipping of the plastic.

Forming and bending: A considerable amount of straight forming and bending is performed in the course of fabricating sheet plastics. For example, in fabricating tubes for packages, the ends of the tube are spun over or beaded against a heated spinning die. The curve of the die rolls the end of the tube over into a perfect bead.

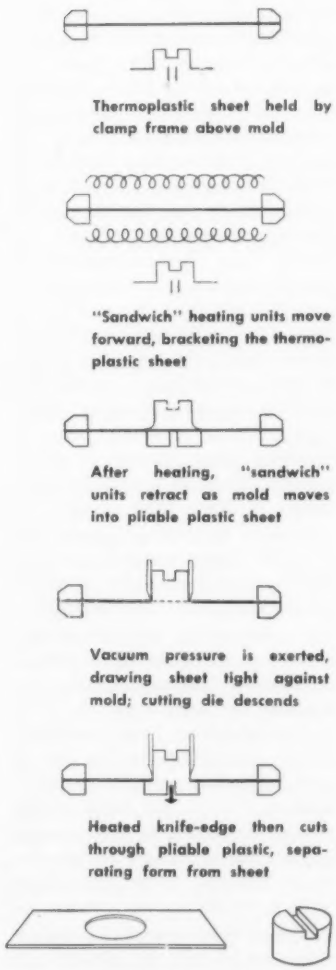
To bend angles in sheets, localized heating is used. The sheet is suspended over a tubular heating element and heated in the area to be bent. The part is then formed in a hinged blender or a sheet-metal brake.

The necessity for forming a part on one machine and trimming it on another has in some instances discouraged the use of sheet forming. Recently a vacuum, drape, and plug forming machine that also trims the product has been developed. The trim is reground and re-extruded, usually along with virgin material.

Special considerations

The most important factor in vacuum forming is the heating cycle and the control of the heater. Heat uniformity is extremely necessary. Rapid heating is also required, not only to provide production speed, but also to obtain maximum results. Experience has shown that a superior product will result if a sheet can be formed with a short heat cycle and a high-temperature heater setting.

The forming characteristics of the presently-available plastics sheet materials are many and varied. It would be virtually impossible to catalog them precisely. However, the following paragraphs summarize the salient points of forming techniques, as applied to various sheet materials, which have been established as a result of practical experience.



Polyethylene is formable between 350 and 375° F. It is slow to heat and equally slow to cool. The heat cycle must be precise for optimum results. Draping action is preferably very slow, and control of the mold temperature as well as the temperature of the clamping frame must be held closely to 130° F. Unless the parts are cooled below 125° F. before they are removed from the mold, considerable warpage will occur. Properly handled, polyethylene can be formed into a wider range of female molds than any other material, i.e., in some instances, polyethylene can be formed into a 90° angle without thinning the material excessively. It is possible to deep-draw polyethylene on male forms; however, considerable care must be taken with drape-assist frames to avoid webbing at corners and between high points.

Styrene copolymers are very flexible in their forming characteristics. Apparently good results can be obtained over a relatively wide temperature range. This characteristic, however, is deceptive since it can be shown on specific tests that a superior product will always be obtained if the heating cycle varies no more than 2 sec. from the optimum. In other words, too little or too much heat will cause high strain and brittleness. In deep-drawing, considerable care must be taken to overcome chill marks or "ridging." This phenomenon, which occurs to some extent in all materials, is very apparent in the styrene copolymers, and is caused by the fact that the area of the sheet that first lands on the top of the plug chills too rapidly; as the sheet is further draped, the cooled portion pulls over the top of the plug, resulting in a ridged effect. Some of the newer formulations show an improvement in this characteristic. The solutions of the problem will vary with each application. In general, the die must be well-heated and the drape stroke must be adjusted very closely.

Until recently, these materials had not been used widely in preprinted applications. It was found that the latent extrusion strains of the sheet varied too widely from sheet to sheet and from batch to batch. Improved extrusion methods have made it possible to control the strains.

Cellulose acetate forms in the temperature range of 300 to 325° F. The critical forming problems with acetate are the elimination of blushing or fogging at points of high strain and the maintenance of clarity close to that of

FORMING AND TRIMMING IN ONE OPERATION

Thermoplastic sheet held by clamp frame above mold

"Sandwich" heating units move forward, bracketing the thermoplastic sheet

After heating, "sandwich" units retract as mold moves into pliable plastic sheet

Vacuum pressure is exerted, drawing sheet tight against mold; cutting die descends

Heated knife-edge then cuts through pliable plastic, separating form from sheet

Trimmed end product is removed from sheet. (Sketches, Vacuum Forming Corp.)

the original sheet. Blushing can be overcome with adequate heat both in the sheet and in the mold.

Cellulose acetate can be successfully formed on molds maintained at a much higher temperature than most other materials. Loss of clarity, irrespective of mold surface, is caused by overheating and burning, which is evidenced by the formation of small bubbles within the sheet. Practice shows that all acetate sheets react best if heated as quickly as possible. Better results can be obtained if acetate is heated in 7 sec. with a 1200° F. heater than in 20 sec. with a 700° F. heater. Thin-gage acetate between 0.005 and 0.010 in. is highly susceptible to webbing between multiple dies and on all sharp corners. There is a definite limitation of draw with these materials in the vertical wall and in depth. Drape-assist frames are necessary and must be carefully handled to achieve best results.

Flexible vinyl copolymers are highly critical forming materials when deep-embossed detail is required. The heat cycle must be controlled with a 1-sec. variation. Molds should be run as hot as possible and no mold temperature control is required. Care should always be taken to use vacuum holes with diameters no greater than 0.012 to 0.015 inch. Care should be taken that there are sufficient holes to assure complete drainage of the die detail and, most important, that rapid air evacuation is provided. Very little successful work has been accomplished in draping the flexible vinyls over deep, straight-wall plugs. The material will not hold together on deep-drawing and will develop webbing which is practically uncontrollable. Preprinting on these materials requires careful control and great patience. Excellent results are being obtained in such end products as wallets, place mats, and colorful Halloween masks.

Rigid vinyl copolymers are easier to form in a much wider range of applications. They are among the few materials which can be successfully drawn over a round plug 12 in. across and 12 in. deep, with a vertical side wall. Close mold temperature control is important since good results require that the mold be no hotter than 120° F.

Although these materials are used in 90% of the preprinted applications today, complete control must be maintained of all forming operations throughout production in order to obtain consistent results. Two seconds variation in heating time is sufficient to throw the printing completely out of register. Care should be taken that the clamping frame be adequately warmed prior to forming so that the heat loss at the edge of the sheet from a cool frame will not affect the printing.

Cellulose acetate butyrate is one of the least critical of the forming materials. Webbing occurs rarely except in the very thin gages and on plugs with deep square corners. Molds should be run between 150 and 160° F. since with both acetate and butyrate, once the shape has been formed, a setting or so-called chilling effect occurs; unlike vinyl and styrene copolymers, acetate and butyrate can be handled with less cooling without losing shape. One problem with butyrate is to prevent overheating which will immediately become evident by a light surface bubbling; larger internal bubbles will develop if the overheating continues. The problem and solution for maintenance of clarity with butyrate is the same as with acetate.

Cast acrylic is a difficult material to form, particularly in gages over 0.063 inch. Simple hemispheres and shallow forms present no problem except to maintain freedom from mold mark-off. To deep-draw the thicker gages of cast acrylic sheet by the drape and vacuum process, it is necessary to overheat the material with consequent loss of clarity, and in many instances even an overheated cast acrylic will not conform to sharp detail with light atmospheric pressures.

Extruded acrylic and straight polystyrene can be formed with less difficulty. Due to the relatively high strains in these materials, considerable care should be taken to avoid warping of the formed piece. To maintain highly polished surfaces, it is important to use highly polished molds and to keep the molds fairly hot during production.

Two-way oriented styrene sheet requires a great deal of control, particularly in the heat cycle. These are often called the split-second materials since heat cycles must usually be controlled within one second. The use of drape forming with these materials is highly questionable and even in forming into female molds only shallow forms and wide radii should be attempted. It is important to run the molds with these materials at a very high temperature.

Plastics Tooling

BY MAX HILRICH* and FRANK L. BOGART†

Plastics tooling interest dates back a quarter-century or longer, but effective applications did not start to emerge until the '40's and it has only been in the last few years that progress has really gone forward. While manufacturers of aircraft, automobiles, and appliances are major users today, plastics tools and dies have found a place in almost every industry concerned with metal-forming or plastics-forming.

World War II created the first big impetus for use of plastics tools, when airplane manufacturers first faced shortages of the metals traditionally used in tooling. Since the initial start, however, the aircraft industry has continued to rely on plastics. One major reason for this has been the fact that, since relatively small numbers of any one model of plane are generally made, the time and expense of machining tools becomes disproportionate in cost.

Automobile manufacturers have turned to plastics tooling because competition dictates frequent and rapid changes in styling. Plastics tools facilitate design revisions since contours can be altered by refacing and other simple methods. In both prototype and production programs, the ease with which plastics tools can be modified helps maintain schedules.

In other fields, initial low cost and fabrication speed of plastics tooling have made it feasible to engineer many new projects. Pilot runs can be quickly and inexpensively started where large investments in metal tooling could not be justifiably risked on untried products.

Materials

Hand-in-hand with the steady increase of application know-how, a big factor in plastics tooling progress has been the development of new and improved materials. Although there has been some experimentation with ethyl cellulose, a thermoplastic material, thermosetting resins have been dominant in all forms of plastics tooling.

Phenolic resins' low cost and handling ease have kept these pioneering materials in some demand. However, in the bulk of applications they have given way to the newer epoxies with their greater strength and durability. Epoxies have also forged ahead of the polyester resins used in combination with fibrous glass and other reinforcements for laminate tools. This is mainly because of the low shrinkage of the epoxies, their better bonding and wetting abilities, and their exceptional stability.

Specific end requirements, however, based on such factors as length of run, degree of dimensional accuracy needed, and stress to which the tools will be exposed, must dictate the final selection of resin. When more than one resin can serve the purpose, relative cost becomes the deciding element.

Combinations of materials are often used. Metal cores increase the compressive strength of plastics-faced dies, while metal inserts can provide a means of piercing and shearing, and can overcome weaknesses in thin sections and sharp radii. Weight and cost can be reduced by making tools with epoxy surfaces and phenolic foam cores. Fillers are used to boost special properties, such as resiliency or abrasion resistance, or as extenders for further lowering materials costs.

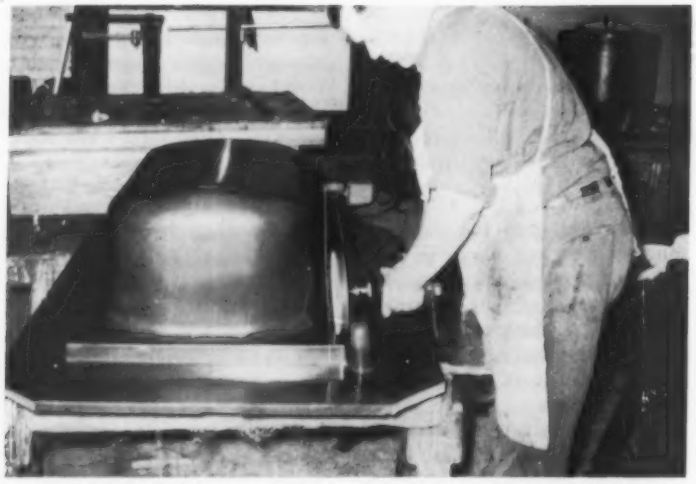
Advantages and limitations

The cost advantages of plastics tools over metal tools are most evident when complicated contours are involved that would be extremely expensive to machine. In general, much of the cost savings with plastics tools are derived from production economies rather than from the differences between the prices of plastics and other materials. Lead time when using plastics tools, for example, is considerably reduced, with tools frequently being produced in days instead of weeks. Barbering and finishing are partly or entirely eliminated by using plastics tools, and equipment requirements are considerably less.

Lighter in weight and more resistant to corrosion than metal tools, plastics tools are also more easily handled and stored. Their ability to be modified makes it faster and more economical to duplicate or revise tool designs.

For prototype production and experimental work to test proper die design, or for relatively short runs, plastics tooling can offer maximum convenience at minimum cost. In this sense, plastics tooling can be an adjunct to, rather than a replacement for, conventional metal tooling. The plastics dies, for example, can be used for production or market-testing a product. When results have been determined, the plastics dies can be supplanted by metal dies capable of absorbing higher costs over a long run.

On the other hand, cases exist in which many thousands of metal panels have been successfully drawn on plastics dies based on special heavy-duty resins cast around fillers and inserts. There are even rugged resins in use today that make possible the production of tools which can stand up to foundry blowers and slingers.



Formulations now about to emerge from the laboratory stage are expected to overcome other deficiencies, e.g., heat resistance and conductivity, that now limit the use of plastics tools and dies.

Basic fabrication methods

Basically, all fabricating methods used for plastics tooling rely on two or three techniques used singly or in combination—casting, laminating, and to some extent splining.

Regardless of what special properties may be incorporated in their formulation, tooling resins

are generally easily-poured liquids which can be stored in unopened containers. After opening, the resin is blended manually or in standard mechanical mixers with a suitable catalyst.

In casting, the catalyzed resin is poured directly against a model or a mold made from a model, usually after the model or mold has been coated with a parting agent.

In laminating, a gel coat is usually first applied to the prepared form to improve surface properties, e.g., abrasion resistance. When this heavy coating becomes tacky, a lay-up is made on the form by brushing an impregnating resin into successive layers of fibrous glass cloth or other reinforcing fabrics, until the required thickness is reached.

Superior new pastelike troweling and splining resins which will not run off vertical surfaces are applied outside male forms as well as inside female forms.

After curing at room temperature or in an oven, the cast or laminate tool is easily removed from the form.

Casting usually involves higher-cost resins, but the extra expense can generally be compensated for by the minimum amount of time and labor involved. Laminate tools are usually more accurate and have greater tensile and flexural strengths than the cast tools. Advantages of both methods are often combined by making tools with a laminate surface and a cast core.

As in the selection of materials and special-property fillers, the use to which the tool will be put must determine both the choice of tooling method and the need for modifying standard tool fabrication techniques. Among the variations in use today are metal-plastics composites; metal backup for plastics facings; phenolic foam cores bonded to epoxy surfaces; and metal inserts. Inserts are either set in place when a die is cast or else installed later by chipping back an area, pouring resin into the cavity, and inserting the metal before curing the resin.

Differences in the properties and reactions of the various available tooling resins may also dictate shifts in basic tooling methods.

Prefabrication steps

Designing a part to be tooled by plastics begins with several basic steps: sketches of the proposed design; miniature clay models; full-size clay models; and finally, a wood master model.

The wood master itself may be put into service as a mold, or a plastics laminate or plaster splash can be taken off it. An existing metal part is sometimes used in place of a mold. Other materials used in varying degrees as molds include vinyl plastisol as well as glass.

Certain rules for preparation of the molds apply to all the resins used for tooling applications; others vary according to the nature of the material.

The general recommendations are as follows: molds must be thoroughly cleaned; their walls should be thick enough for rigidity and strength, but not so thick that they will lengthen drying and curing times.

Porous molds require drying and sealing. Several coats of a sealant are often applied until a glossy finish is obtained; light sanding with 400 grit paper between each application is another practice frequently followed. If weaves or wave-like surfaces are present, they must be smoothed down. Blemishes are sanded off and hollows filled in.

This close attention to finishing is especially important because of the fact that casting resins accurately reproduce the surface of the mold against which they are cast. Any imperfections in the mold surface will therefore show up as imperfections on the plastics tool. If a "mirror-smooth" finish is desired on the tool, it is advantageous to buff the mold surface to achieve the desired smoothness.

Sealing porous surfaces is followed by high-luster wax buffing and application of a parting agent. Time spent in these mold-preparation procedures will be saved later by elimination of tool-finishing steps.

Nonporous and smooth plastics molds need only be waxed and a parting film applied. Plastisol and glass generally require no parting agents at all.

Metal-forming dies

Many types of tools are made for forming metal sheets of varying thicknesses.

Stretch dies: Plastics stretch dies are among the most prevalent tools of this kind. They often have working face areas of well over 100 feet and are used in conventional stretch presses, where a metal sheet is gripped by clamps and pulled over the die by mechanical or hydraulic power. Plastics dies are particularly sat-

isfactory for this use because they can be made to have a glasslike surface which eliminates die marks on the formed metal parts. They are used widely in the aircraft industry as well as for making refrigerator components and for forming automotive panels.

While laminate shells, cross-ribbed for strength, are sometimes used for stretch dies, casting resin poured into a female mold is the more common technique. A foamed core can be used to reduce the die's cost and weight. In such case, a cured core of foamed phenolic or other resin is suspended in the mold cavity and the casting resin poured around it. An alternate technique is to secure sections of foamed resin to a metal or Richlite backing, then to suspend this in the cavity while the casting resin is poured through holes in the plate.

Draw dies: Plastics draw dies offer savings in initial cost, lead time, and maintenance. They are sometimes made with cast cores and laminate surfaces. Their primary use is for developmental work and the drawing of prototype parts, but they have also been used to draw fairly large numbers of panels from thin-gage steel and aluminum, and in addition have been adapted to short runs of heavier cold-rolled steel.

Hand hammer forms: Plastics hand hammer forms are particularly useful in automotive design programs, where special tools may be needed to produce a few metal parts.

Hand hammer forms may be cast solid, or made by pouring a casting resin over a foam core in a retaining frame. Precision-cast inserts of brass and zinc alloy can provide for exceptionally sharp contours. These inserts may be set in the mold prior to casting and locked into place by slots or bolt heads protruding into the plastic. They can also be set in during a later phase of the operation by chipping out a section of the form and casting the inserts in place with the plastic.

Drop hammer dies: Plastics are often combined with other materials in making drop hammer dies. In one successful method, a filled resin is cast inside a laminate for the bottom half of the die. This part of the die is then placed in a frame to serve as the mold for casting a resilient epoxy face on the corresponding punch, which will have a lead or Kirksite core. Since a parting agent is used, the two halves of the drop hammer can be easily separated.

Other variations in drop hammer die design include plastics punches with metal bottom dies, punches with laminate faces over cast bodies, and punches with steel weldments for added strength.

Rubber press hydro-forming and hydro-static dies are made of both casting and laminating resins for forming metal parts into odd shapes.

Fixtures, jigs, and gages

Construction of fixtures and gages accounts for a large amount of plastics tooling materials.

Flange-checking fixtures fabricated of plastics are accurate and inexpensive, since they are made directly from the master model or its duplicate. They are used to check contour flanges and hole locations of parts.

Lightweight, inexpensive, yet durable, plastics fixtures and gages are made to duplicate complicated shapes by hand lay-up of epoxy resins and fibrous glass cloth directly onto master models.

Plastics holding forms can be made by suspending an actual part in a frame and waxing and coating it prior to pouring casting resin around it. After curing, the part is separated from the casting by sawing the casting in two. Each half of the casting will retain the contours of the piece being duplicated.

Similarly, by casting or laminating against a part, plastics holding fixtures for secondary operations can be made, as can other fixtures for trim, drill, routing, assembly, plating, welding, and other functions.

Duplicates and models

Laminated plastics duplicate models and Keller models are widely used, particularly in the automotive industry.

Gel coats and laminating resins are applied over a wooden die model. A framework of tubing or sheet stock is then bonded on to serve as a spotting fixture. A laminate skin is made on this spotting rack, and a framework and base, as well as locating pads, are provided.

Duplicate models made in this way are often sent out by automobile manufacturers to their various accessory makers and assembly plants for reference.

Laminated or cast plastics study parts are used to plan design, tooling, and assembly operations.

Foundry applications

Plastics resins, particularly the epoxies, are beginning to make deep inroads into foundry and pattern-making work.

Unfilled and filled casting res-

Cast plastics dies, here used to draw a complex automotive part, are ideal for developmental work because of ease with which design changes can be made

Resin-impregnated fibrous glass cloth is laid up against a die model in a frame in initial step in production of a Keller model. (Photo, Marblette)

ins, laminating resins, and troweling resins are becoming more and more popular as materials for patterns that do not require the costly machining and time-consuming finishing of metal patterns.

Plastics resins are also being widely adopted as a coating for wooden patterns and in foundry repair work for patching worn spots in metal core boxes.

Particular savings are gained with plastics materials when there is a need for multiple patterns, or for many duplicates of core boxes, core prints, or match plates.

Specially - developed plastics materials are used for fabricating core driers that are used in dielectric baking.

Laminating resins are frequently used with abrasion-resistant gel coats for constructing large and relatively complicated patterns.

Plastics-forming tools

Plastics tooling for plastics fabrication finds a major outlet in vacuum forming and in other processes for shaping plastics films and sheets by applying heat and pressure.

Vacuum forming plastics dies can be fabricated faster than machined metal dies. Their dimensional stability permits them to be used interchangeably on the press platen for multiple forming, and they faithfully reproduce even the most intricate detail. Mass production is facilitated by the ability of plastics dies to be revised or repaired quickly and easily.

Cast and laminated epoxy production molds have also been used for forming large and small reinforced plastics parts—by vacuum bag molding and other techniques. Among the reinforced plastics items turned out on plastics molds have been one-piece bathtubs and huge sections of prefabricated home swimming pools.

Plastics matched dies are used for low-pressure molding of plastics components. Plastics pattern duplicates have helped speed up mass production of products made by latex-dipping. Plastics tools have also been used for forming foamed plastics parts such as automobile cushioning and crash pads.

Forming acrylic

Both cast plastics tools and laminated reinforced plastics tools are used to shape precut acrylic sheets, particularly in the aircraft industry. These tools form windows, canopies, astrodomes, landing light covers, and other plastics parts. The basic technique used is manually to drape the preheated acrylic sheets over the forming tool. An overhead clamp holds the sheet while a vacuum circuit in the tool pulls the sheet into the required shape, holding it in place against the tool while it cools and hardens into the desired form.

Heated acrylic sheets are also formed by the application of pressure, without the use of a vacuum, on cast phenolic and epoxy dies. This technique has been used in the production of very large plastics signs and displays which frequently have irregular contours.

Casting and laminating resins are also used in the aircraft manufacturing field for plastics-forming applications requiring great accuracy and close tolerances.

Advances and prospects

Future significant applications in the field of plastics tooling are expected to develop as a result of the work now being done on new plastics resins. Epoxy resins and special high-heat-resistant resins seem to be receiving the major share of attention.

Forming of hot metals, for example, is becoming more feasible with the introduction of new tooling resins with a heat resistance of approximately 600° F.

With such heat resistance, and with the development of resins capable of withstanding more impact and abrasion, foundry field uses should continue to expand. Experiments in fabrication of shell mold patterns are currently making headway.

Production molds of plastics with improved heat transfer should also create further inroads in the plastics-forming field, particularly in injection molding.

Development of epoxy rubber-like resins that have high-impact resistance and do not harden with age is already leading to increased uses for plastics drop hammer forms.

CASTING ACRYLICS

BY JOHN O. BEATTIE*

The casting of plastics materials differs from other molding techniques in that the starting material is a liquid monomer which solidifies by polymerizing within a mold to the finished shape. Casting sheets is usually done at moderate temperatures.

There are many different monomers which can thus be cast into sheets. The best known of these is methyl methacrylate, the polymer of which has been sold as cast sheet. Sheets produced by casting have superior optical properties[1], since their surfaces reproduce exactly the polished surfaces of the glass molds in which they are cast. Other properties—tensile and impact strength, surface hardness, and thermal and electrical coefficients — compare favorably with molded sheets.

Methyl methacrylate

Casting-grade methyl methacrylate monomer is a water-white liquid which has the following physical properties:

Specific gravity	@ 25° C.	= 0.940
Viscosity	@ 25° C.	= 0.56 cp.
Refractive index	n_D^{25}	= 1.4118
Boiling point	@ 760 mm.	= 100-101° C.

The chemical formula of methyl methacrylate is

$$CH_2=C(CH_3)-C(=O)-OCH_3$$

and since the molecule contains only one active group, methyl methacrylate polymerizes in linear chains to yield thermoplastic sheets.

Of all the materials that can be cast into sheets, methyl methacrylate has the most interesting properties. Cast methyl methacrylate sheets have good tensile and impact strengths and excellent weathering properties. They can be readily machined, and on more or less conventional equipment. The material can be formed to almost any simple or compound curvature, and its high optical clarity, luster, and sparkle make this a premium material.

As received from the manufacturer, methyl methacrylate monomer contains 20 to 60 p.p.m. of hydroquinone inhibitor. In order to obtain maximum clarity, it is necessary to remove the inhibitor contained in the monomer to less than one part per million. This cannot be accomplished by ordinary distillation, since the hydroquinone itself is somewhat volatile. A carefully designed fractionating column is required.

Uninhibited methyl methacrylate monomer can be stored for some time if it is refrigerated at around 4° C., but it is best not to accumulate large quantities once the inhibitor is removed.

Casting molds

In preparing a casting mold, two sheets of glass are carefully cleaned to remove all dirt and lint which could create flaws in the finished cast piece. This glass can be selected plate glass, free of scratches and other surface imperfections, or tempered glass (Herculite, Tuf-flex). Tempered glass has the advantage of great strength and resistance to thermal shock, though it is by no means as unbreakable as might be supposed before one has actually handled it.

The tempering of glass plates is covered by a considerable number of patents, and all plate glass which is tempered in this country is done so under license[2]. Furnaces can be obtained to temper plates of glass, but problems of yield, flatness, and high initial cost have to be considered carefully. It is also entirely possible that homemade tempering of glass plates can be less effective in producing ultimate hardness than that obtained from commercial manufacturers.

The two plates of glass, carefully cleaned and dried, are placed face to face and spaced the required distance apart by means of a "gasket" which can be an extruded elastomeric material such as plasticized PVC, or a solid material such as aluminum or steel covered with paper and cellophane tape. Since, however, all monomers undergo considerable shrinkage as they polymerize, use of solid gasket material requires that the gasket be removed during cure to permit the glass plates to come together and allow for the shrinkage.

The mold, or cell, composed of the two plates of glass separated by the gasket, is then clamped together, with one corner of the mold normally left open for the introduction of the resin monomer. The clamped mold is then laid in an inclined position for filling.

Pouring the resin

The mold is loaded by pouring the resin through a specially designed funnel (Fig. 1, p. 748) into the corner opening. Since the plates of a glass mold of any size are quite flexible, it is necessary to introduce exactly the correct weight of resin to get a finished sheet of uniform thickness. Fill-

[1] The term "optical properties" is a catch-all which includes such properties as transmittance of visible and ultra-violet light, haze, angular deviation, and minor defects. If the sheet is to be accepted for aircraft applications it must meet the rigorous requirements of MIL-P-5425A. A ¼-in. sheet, for example, must have 90% transmission of visible light but must not transmit more than 5% of incident UV in the 290- to 330-mμ range. Its haze value must be less than 3% and it cannot average more than one minor defect for each 4 sq. ft. A minor defect is a small bubble, a scratch, an imbedded particle. It must not deflect light more than 7 min. of angle from a perfect straight-line path. A 7-min. deflection would cause an object 1 mile distant to appear 10 ft. out of place!

[2] American Securit Co.

Fig. 1: Accurately weighed-out sirup is poured from stainless steel pitcher into tilted mold through funnel especially designed for this operation

ing the mold to the top would cause the glass to bow out under the hydrostatic pressure of the liquid, and would yield a sheet considerably thicker at the center than at the edges.

The mold having been charged, the opening in the gasket is closed and the mold lowered to the horizontal position. The operator taps the mold (Fig. 2, below) to spread the charge and the mold is transferred to a rack and placed in an oven where the resin is cured. The curing temperature, of course, depends on what resins and catalysts are being used, but in general it is between 45 and 70° C. In many cases, a single fixed curing temperature is not satisfactory; if it is necessary to change the temperature during the cycle, a suitable time-temperature control must be installed on the curing oven.

Curing time

The time required to produce a full cure in the mold depends not only on the temperature, but also on the catalyst being used, and on the sheet thickness. Acrylic casting resins evolve heat very suddenly during the polymerization; it is just as much the function of the oven to remove this heat as it is for it to provide the temperature required to start the reaction. It is a good general rule in designing casting ovens to have as high an internal air velocity as possible. If the air velocity is not high enough to remove the heat of reaction, the temperature of the casting will rise. It can easily rise high enough to destroy the sheets being cured; in extreme cases, when the thermal shock is of sufficient magnitude, the glass molds may actually shatter.

A possible method of absorbing exothermic heat, at least in the case of methyl methacrylate, is to mix powdered polymer with monomer to produce the casting sirup.[8] The exothermic heat given off by the monomer is almost counterbalanced by the heat of the solution of polymer as it dissolves in the monomer. It is claimed that thick methyl methacrylate castings can be produced in this manner and that very little exothermic heat is given off.

For most materials up to ⅛ in. in thickness, curing time can be held to approximately 16 hours. But thicker materials may require more than 16 hr. curing time, since it takes much longer to remove the exothermic heat from a thick piece than from a thin one. In the case of 1-in. and thicker slabs, the curing time may be as much as a week.

After curing is complete, the molds are withdrawn from the oven and cooled, the clips and the gasket are removed, and the glass plates are separated from the now-solid plastic sheet. The plastic surfaces, faithful reproductions of the polished glass surfaces of the mold, are optically clear and ready for use without further processing. Usually, the plastic sheets are masked prior to shipment. Masking consists of applying paper coated with pres-

[8] U.S. Patent 2,468,094.

Fig. 2: Operator lowers tilted mold to the horizontal while tapping it to assure even spread of the charge through the entire mold

-sensitive adhesive to both sides of the plastic sheet. A sheet so protected can be fabricated without risk of marring the mirror-smooth surfaces.

After the plastic sheets are removed from the molds, the glass plates go back to the cleaning and assembly operations previously described, and the cycle is repeated. The plates of glass can be used hundreds of times if they are properly cared for, and the mold cost per cast sheet is very low.

Shrinkage in the mold

As already mentioned, any mold in which resin monomers are to be polymerized must be designed to allow for the shrinkage which occurs during the cure of the resin. Polymerization shrinkages of acrylic resins range from 15 to 21% and the shrinkage must be taken up by allowing the two glass plates to come closer together during the curing process. If they cannot come together, the sheet will separate from the plates and will be spoiled.

The material naturally seeks to shrink equally in all directions. In the early stages this is possible because the sirup has a relatively low viscosity and flows readily under the stresses set up by volume changes. Later, however, the viscosity becomes very high and at the same time the sheet adheres to the mold plates. Movement in the planes parallel to the plates is severely restricted, so all cast sheets end up with cured-in stresses. These stresses can be alleviated, or at least greatly reduced, by annealing the cast sheet after it is out of the mold. Methyl methacrylate sheets, for example, are normally annealed by reheating to about 150° C. and then cooling slowly. During this procedure the sheets shrink about 2% and the cured-in stresses are almost completely relieved.

The annealing or shrinking of methyl methacrylate sheets is quite an art, since even slight variation in conditions will produce out-of-flatness or incomplete annealing. Localized optical flaws appear in shrinking which are invisible as the sheets come out of the mold. The would-be manufacturer of cast methyl methacrylate sheet would do well to examine this part of the process most carefully.

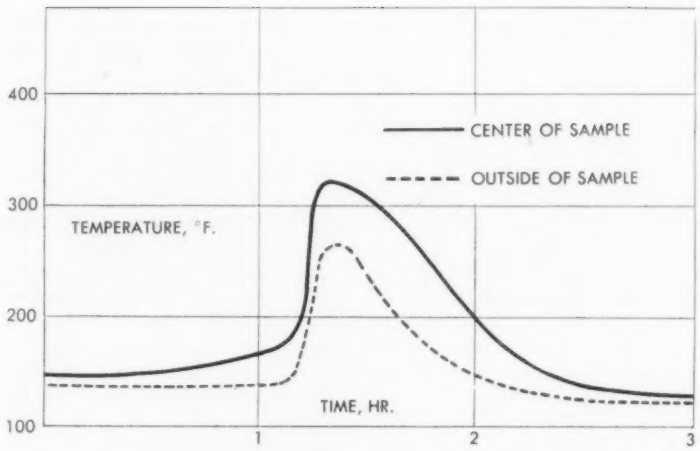

Fig. 3: Typical curing-reaction exotherm curves for methyl methacrylate. This particular sample was a 2-in.-diameter cylinder that was cast in a glass jar immersed in water at 50°C. "Outside" temperature was measured by thermocouple that had been placed at the resin-glass interface

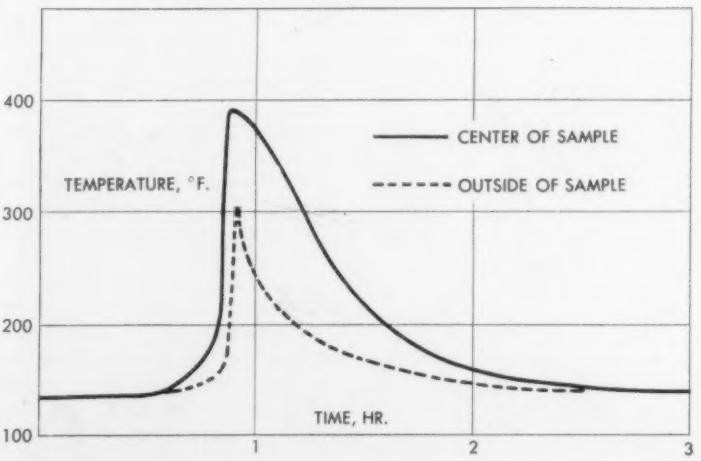

Prepolymerization

Another way of reducing the bad effects of shrinkage in the mold is to reduce shrinkage. To this end, most thermoplastic resins are prepolymerized to a "casting sirup." The use of such a sirup not only lessens the polymerization shrinkage in the mold (because some polymerization shrinkage has already taken place outside of the mold), it also offers three other advantages: 1) the curing time is reduced; 2) less exothermic heat is evolved during the cure; and 3) the sirup is less likely to leak from the mold.

When handling methyl methacrylate monomer, for example, the uninhibited monomer (which is a clear, colorless liquid of about the same viscosity as water) is heated in the presence of a catalyst, whereupon it begins to polymerize, gradually becoming more and more viscous until it reaches the same consistency as molasses (in June, not January!).

One technique for performing this operation is to heat the ma-

Fig. 4: Temperature-time curves for methyl methacrylates with 10% methacrylic anhydride. Temperature rose much higher than with pure methacrylate (see Fig. 3, above), although the same conditions obtained. The rate of rise at the surge is approximately twice as fast

terial in batches of about 150 lb. in steam-jacketed kettles. A small amount of azo catalyst is added to the mix, which is then heated to the required temperature for the required length of time. During this period, the material is mechanically agitated.

Suitable catalysts for this purpose include benzoyl peroxide, t-butyl perbenzoate, lauroyl peroxide, isopropyl percarbonate, and other similar types of catalysts. Recently a proprietary catalyst, azoisobutyronitrile,[4] has been suggested for this purpose.

Thickening of methyl methacrylate monomer to a sirup requires careful control, particularly during the cooling phase. With inadequate cooling facilities, the contents of the kettle may heat up beyond their boiling point, causing the vapors of methyl methacrylate to boil out of the kettle, and creating a very serious fire hazard.

Since methyl methacrylate monomer and casting sirup have a specific gravity less than 1, a fire of this type cannot be extinguished with water. A mixing room of this type should contain other means of extinguishing such fires as they occur. All fixtures in such a mixing room should also be explosionproof.

Rate of exotherm

Figure 3, p. 749, shows graphs of temperature *vs.* time during cure of a cylindrical methyl methacrylate casting 2 in. in diameter. For the first part of the cycle, virtually no heat is given off. At a crucial stage, the viscous liquid suddenly becomes an undercured solid, and at this point practically all of the heat of polymerization is liberated. An ordinary curing oven which would be satisfactory for the other materials, cannot remove fast enough the big slug of heat which is evolved with almost explosive rapidity. If the sheet is a little too thick for the oven to handle or the catalyst concentration is a little too high, the sudden burst of heat begins to boil the monomer and large bubbles form between the glass plates. The internal pressure mounts fast and the costly glass molds are likely to shatter under the effect of the thermal shock.

Special care must be taken to remove this heat. Since the amount of heat given off is proportional to the amount of material in the oven, it is the large batches of material and the thicker sheets that are the most difficult to keep under control. Unfortunately, loss of control is most costly when control is hardest to maintain—when the oven is running near its capacity both in molds and in resin. In curing methyl methacrylate, therefore, air velocities and air turnover in the oven must be as high as possible in order that the heat that is given off at the critical point of the curing cycle may be quickly removed. As an extra safeguard, the oven should have an external vent so that cold air can be brought in as needed.

Since water is a much better heat-transfer medium than air, an extra degree of control is gained by curing thicker sheets, e.g., ½ in. or over, in a water bath. It is only necessary to keep the molds in the water bath until the resin has safely passed the critical point. After this, the cure may be completed in air.

Copolymerization

Methyl methacrylate can be copolymerized with a number of other monomers. It copolymerizes readily with most of the available acrylate and methacrylate esters, as well as with styrene and vinyl acetate. Copolymerization with cross-linking materials such as CR-39, diallyl diglycolate, diallyl maleate, etc., yields infusible polymers and properties intermediate between those of the cast pure resins. Some of these copolymers are valuable commercially because of their increased solvent and craze resistance, though this is obtained at the expense of formability. In some cases, such as the copolymerization of methyl methacrylate with methacrylic anhydride, the problem of exothermic heat is greatly aggravated, so that the difficulty of safely casting some of these materials becomes very great. The temperature-time graph for the curing of a 2-in. cylinder of this copolymer is shown in Fig. 4, p. 749. Note how much higher the temperature peak is than in Fig. 3, p. 749, for methyl methacrylate alone (255° F. rise in center *vs.* 165° F.). Note also that the slope of the peak in Fig. 4 is steeper—the rate of heat-up is about 1.5 times as fast.

THERMOSETS, LIQUID AND CAST

BY MAX HILRICH*

New thermosetting compounds are constantly being developed to supplement the wide choice of cast epoxy, phenolic, and polyester resins that are available to industry.

Distinction should be made between those resins which are furnished to fabricators in already-cast form and those supplied in liquid form for casting and related uses. In the former area, the phenolics retain their dominance for use in fabrication of consumer items and many kinds of parts for industrial use. The liquid phenolic formulations are used primarily for casting and serve such special needs as bonding, laminating, sealing, surfacing, and potting. Liquid epoxies have become well-nigh indispensable for plastic tooling, but phenolics also are still functioning in tooling programs. Polyester and epoxy liquid resins are widely used to impregnate electrical and electronic components (see "Potting and Encapsulation of Electrical Components," p. 753). By combining fibrous glass and other reinforcing materials with epoxy and polyester liquid resins (and to some extent with phenolic

*Research Director, The Marblette Corp., 37-21 30 St., Long Island City, N. Y.

References were prepared by the editors.

resins), exceptionally strong products can be turned out by the manufacturer.

Cast phenolics

Laboratory formulation is followed by 14 to 18 hr. of compounding in huge kettles. High heat condenses formaldehyde and phenol in the presence of a catalyst, and excess moisture is removed by vacuum distillation.

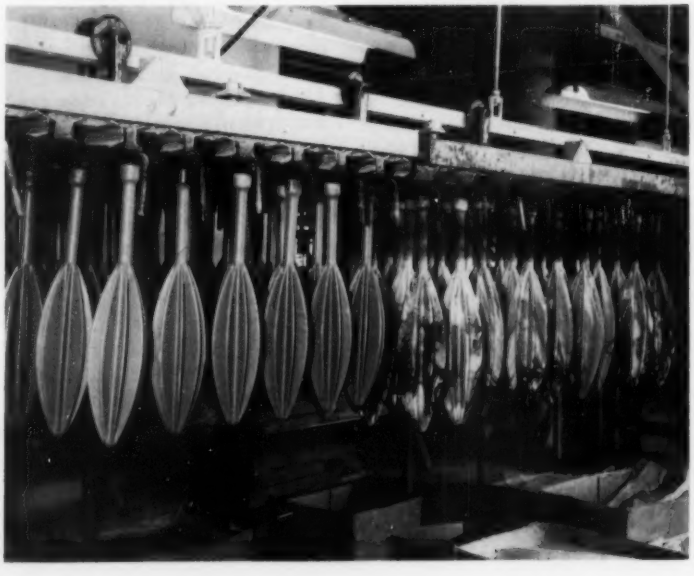
Coming from the kettle in pure form, the required phenolic compound is poured into a heated lead mold produced from a steel arbor used as a master pattern. It is then oven cured and removed from the mold. A diversity of standard and special shapes is produced in this way—cylinders, tubes, rods, sheets, slabs, and other forms.

These phenolic castings are hard and rigid, with high strength and good resistance to combustion, fungi, acids, and extremes of temperature. They are readily machined with standard tools.

Cast phenolics owe much of their popularity to eye appeal. They range from pastel to dark colors, in varying degrees of opacity or transparency, and with mottled effects available to simulate marble and gems. They are used for fabricating costume jewelry, umbrella and cutlery handles, trophy bases, cigarette holders, hairbrush backs and shaving brush handles, ornamental bottle tops, and other items whose acceptance relies on visual attractiveness.

From the fabricator's point of view, a prime advantage of phenolic castings is their ability to be machined as easily as hard woods, with low setup costs. Standard tools are used in finishing the cast phenolic shapes by wet and dry grinding, sawing, drilling, tapping, turning on lathes and spindles, sanding, lapping, hand polishing, buffing, and tumbling.

Phenolic castings are available in a range of marble-like mottled effects that make them useful for trophy bases, lighters, etc. (Photo, Marblette)



Casting resins

Versatility and relatively low cost have spurred the use of *liquid phenolic resins* for casting. They have long shelf life when stored in cold rooms in unopened containers. When about to be used, they are brought to normal room temperature. In an acid-resistant container, the resin is mixed with an appropriate hardener, either manually or mechanically, at low speed (generally 30 to 60 r.p.m.) to entrap a minimum of air in the mixture, dispose of bubbles, and forestall crazing of the finished casting. Polymerization usually is achieved with controlled heat, but room-temperature cures or time-saving combinations of oven and room cures also take place.

Liquid phenolic resins produce castings with good dimensional stability, low shrinkage, and high resistance to heat and acids.

Liquid epoxy casting resins exhibit an even more striking range of advantageous properties. In addition to negligible shrinkage and dimensional stability, they offer strength and rigidity, resilience (in special formulations when required), ability to stand up under abrasion and impact, and resistance to crazing, chipping, and cracking. They are found to be very durable, even when extreme wear is anticipated, as in applications like draw dies

Metal mandrels coated with a protective epoxy resin do not develop pits and fissures when dipped into hot latex to produce beach balls. (Photo, Marblette)

and other metal-forming tools, routing fixtures, and foundry dies. They require little or no finishing.

Except in special circumstances, such as in the manufacture of special-purpose tools, epoxy resins require no heat for polymerization. They ordinarily set at room temperature, with the aid of noncorrosive hardeners. Some manufacturers further simplify curing by prepackaging resins with the required amount of the proper catalyst.

Unlike phenolic and epoxy casting resins, which are available in standard as well as special forms, *polyester resins* are most often custom formulated to meet specific requirements. Usually furnished as comparatively thin liquids, they must be blended with small and carefully measured amounts of catalysts to assure proper cure.

However, polyester resins for tooling uses are limited by their inability to match the other resins in such properties as high strength and low shrinkage, but they are prominent in potting and reinforced plastics applications.

Tooling applications

Plastic-forming and metal-forming tools may be made entirely of one resin, a combination of resins, or a combination of plastics and other materials. For example, epoxy hand hammer forms used in prototype production to establish a final die design may have a phenolic foam core to reduce cost and weight. Heavier-duty tools, allowing for complex contours and standing up to longer runs, may have a laminated face built up with a gel coat. Metal inserts may also be used at points of stress. Durable drop hammer punches have been made by casting an epoxy face on a lead alloy body.

Plastic gages, fixtures, draw and stretch dies, rubber press forms, hydroforming dies, and other tools are now standard production adjuncts in the automotive, aircraft, appliance, and other industries. Foundries have learned that improved epoxy resins provide tools that can stand up to blowers and slingers, and are using an increasing number of plastic patterns, match plates,

Cast plastic vacuum forming die is produced by pouring liquid resin into plaster model. (Photo, Marblette)

core boxes, and core prints. (For a complete discussion on the use of plastics tools for forming metal or plastics, see "Plastics Tooling," p. 743.)

Plastic tools have gained acceptance because their light weight permits easy handling, they can be stored without danger of corrosion or rust, and they create cost savings by reducing lead time and virtually eliminating finishing. Since phenolic and epoxy tools can be readily revised by recasting, refacing, chipping away, or adding material, quick changes can be made.

Not only do plastic tools save many man-hours, but they also bypass the complex equipment required to produce metal and wood tools. They are constructed principally by casting, but laminating is also involved. Many tools with cast cores have laminated faces for added strength.

Epoxy and phenolic tools have been fabricated in days or even hours. While particular applications may entail variations, a basic method begins with making a plaster mold from a model. A sealant and parting agent are then applied to the mold and the liquid resin is poured into the mold cavity. After curing, the finished part is separated from the mold and can be put to work with a minimum of delay.

Reinforced plastics

Thermosetting resins, primarily epoxy and polyester resins, can be combined with glass fibers and other fillers and reinforcing materials in the manufacture of industrial or architectural components and durable consumer products that range from luggage to boats, automobile bodies, and swimming pools.

A recent trend has been toward the use of epoxy production molds in reinforced plastics fabrication.

Laminate tools are frequently constructed by laying successive thicknesses of plastic resin and a reinforcing material onto a form. Such tools are often used to produce items which demand painstakingly close tolerances, such as wing tips and jet radomes for civil and military aircraft.

Special uses

Thermosetting resins now come in so many forms for so many different purposes, that any listing of their uses would lose its up-to-dateness almost as soon as it was written.

However, among recent strides made by these resins, particularly by the epoxies, are:

Rubber-like resins and resins that combine resiliency and toughness for gasketing, etc.

Maintenance paints and protective varnishes with tested ability to guard machinery, piping, and steel and concrete structures from the adverse actions of fumes, fluids, acids, alkalies, solvents, caustics, and corrosives. These coatings adhere firmly to virtually all surfaces. They are especially adaptable to latex dipping where they smooth the finish of metal pattern duplicates and prevent development of pits and fissures during repeated immersion.

Dimensionally stable and durable cast and laminate dies for thermoforming processes.

Low-viscosity epoxy resins particularly suitable for vacuum-bag and contact-pressure laminating techniques.

Resins with putty-like consist-

...y, for troweling and splining applications, that can be spread on vertical or horizontal surfaces.

POTTING AND ENCAPSULATION OF ELECTRICAL COMPONENTS

BY F. G. FIRTH*

Experience has shown that most failures in electrical devices are the result of insulation breakdown, caused by heat, aging, or the presence of voids, and by a contributing mechanical fatigue of the insulation by scraping, bending, or by vibrational forces in rotating devices, such as motors and generators.

The solution to this problem is to completely impregnate and cover exposed current-carrying circuits with a 100% solids, low-shrinkage, high-mechanical-strength, high-dielectric-strength material that is thin enough to penetrate the structures and can set up hard within a reasonable length of time. A useful class in this area is called potting resins.

*Consulting Chemist, 3221 Barry Ave., Los Angeles 66, Calif.

References were prepared by the editors.

Encapsulation is the covering of a device with an electrical insulating material, whereas potting is the complete penetration of the voids in the device with the insulating resin.

Available resins

Resins suitable for electrical impregnation are either thermosetting or thermoplastic. The terms are somewhat misleading, however, and have little to do with the actual service temperature of a given material. Teflon or glass could be called thermoplastic materials, and yet they have much higher useful service temperatures than, say, a thermoset polyester. The most practical materials are discussed below.

Phenol-formaldehyde resin: This material is available for potting use as a thick sirup which can be catalyzed. Polymerization will produce condensation by-products and water that must be removed in order to produce a void-free casting. This requires a long, slow cure and application of vacuum. The electrical and mechanical properties of the finished polymer are not very good and the shrinkage of the polymer is quite high.

Polyesters: The term polyester covers a wide range of materials that have one thing in common: the copolymerization agent employed. For electrical impregnation purposes monomeric styrene is used, which permits a low-viscosity liquid to be made. This may be polymerized with organic peroxides. For compression molding, the copolymerization agent is

Diagrammatic representation of potting by vacuum method, showing the successive steps in the process. Assemblies to be potted should be prebaked before being covered with resin, or else considerable foaming action will take place

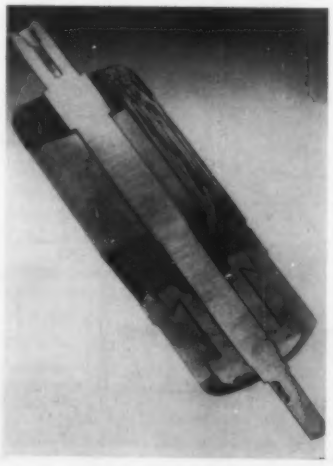
diallyl phthalate, used because of its higher vapor pressure.

The polyesters themselves are either solids or very viscous liquids, and the addition of styrene reduces the viscosity. Unfortunately, the more styrene is used, the higher the shrinkage upon cure, which may be as high as 10% by volume.

This shrinkage, combined with poor wettability of surfaces, gives results that are not all that can be desired. The solvent action of monomeric styrene upon some wire enamels is rather severe and can cause a prevalence of shorted turns.



Silicones: The silicones include a wide variety of chemical structures that have little in common other than the presence of chemically combined silicon.

Since they are expensive, they are used in potting only for special jobs that cannot be done by cheaper products. Silicone formulations are available to make casting or impregnating resins, elastomers, and resilient or rigid foams. The materials are generally difficult to process, and are used mainly for Class H conditions.

The disadvantages are poor solvent resistance, poor adhesion to surfaces, and long curing times. Some of the advantages are good properties at high and low temperatures, high thermal conductivity, slow combustion rate, and good ozone resistance. Electrically, they rate fair to good.

Polyurethanes: The reaction of a diisocyanate with polyfunctional groups can produce materials that will range from elastomeric to rigid, and may either be dense solids or foams. Depending upon the nature of the functional reactants, there may be produced polyurethanes, polyureas, polyamides, or a complex structure of all three.

Epoxy-potted motor armature, sawed in half to show thoroughness of impregnation. (Photo, Epoxylite Corp.)

For an impregnating, coating, or casting resin, tolylene diisocyanate is commonly employed because of its availability and lower cost. The reactant is usually a polyester with a low acid number, and hydroxyl terminal or intermediate groups, for cross-linking with isocyanate.

A simple example of such a material is castor oil, which contains three hydroxyl groups, spaced along a long carbon chain.

Small amounts of a tertiary amine or cobalt naphthenate are sometimes added to shorten the cure cycle.

The group is characterized by excellent adhesion, ability to wet surfaces, low viscosity, good electrical resistance, toughness, and low shrinkage.

For printed circuit boards, the polyurethanes provide an excellent material for protecting the exposed elements from abrasion, water, solvents, and low-temperature cracking.

The high impact resistance of the elastomeric types is very useful in missile and aircraft circuits, where extreme vibration and acceleration stresses are encountered.

All in all, the polyurethanes are very versatile and useful mate-

Encapsulated stator for a large random-wound motor which is to be used in a metal grinder. (Photo, Epoxylite Corp.)

rials for potting and encapsulation, when they are correctly employed.

Epoxy resins: These resins are probably the most versatile and most widely useful of the available compounds. The uncatalyzed resin is offered in a number of forms, ranging from 250-cp. liquids to high-melting-point solids. The chemistry and mechanisms of cure are well understood, and highly reproducible results can be obtained with normal care.

The useful pot life and final properties are determined by the class of resin and the curing agent used. The liquid resins, which are most commonly used for impregnation, can be polymerized with either a condensation-type curing agent, or with a catalyst. The former can be an aliphatic or an aromatic diamine, such as diethylene triamine or paraphenylene diamine. Condensation hardeners of another type are the acid anhydrides, such as maleic, phthalic, or pyromellitic anhydride. The catalyst-type curing agents are usually either tertiary amines such as piperdine, or an active Friedel-Crafts catalyst such as boron trifluoride. Free alkalies such as sodium hydroxide can also promote polymerization.

Catalyst-cured systems usually employ about 1% of the catalyst, whereas for a hardener cure, between 5 and 50% of the total volume might be used, depending on the hardener and resin used.

Generally it may be said that the amine-cured system has the

greater utility for electrical work, both for reasons of superior results and for ease of handling.

The aliphatic diamines can cure a liquid epoxy resin at room temperature, or with little external heating. Aromatic-amine hardeners, though they require heat for cure, yield considerably better finished properties.

The epoxy resins have excellent adhesion to most surfaces, low shrinkage upon cure, low solvent or water absorption, good wettability, and low solvent power for insulating enamels. For these and other valid reasons the epoxy resins are being used more and more for electrical insulation.

Fillers and modifiers

Fillers are added to electrical potting and encapsulation resins for various reasons: to lower cost, to improve physicals, including toughness, to decrease coefficient of thermal expansion, to improve electrical properties, to raise thermal conductivity, to improve appearance, and to change the flow characteristics of the uncured resin.

In an encapsulation application where a nonflowing paste is required to be applied to a vertical wall, various thixotropic fillers can be used. Among these are the large-surface-area silicas, such as Santocel or Carbosil.

Toughness is improved by adding a reinforcing fiber such as chopped glass or asbestos.

To improve thermal conductivity and decrease thermal expansion, a dense filler such as tabular alumina, or fused-quartz powder is useful.

Arc resistance is considerably improved by adding electrical grades of classified mica powder.

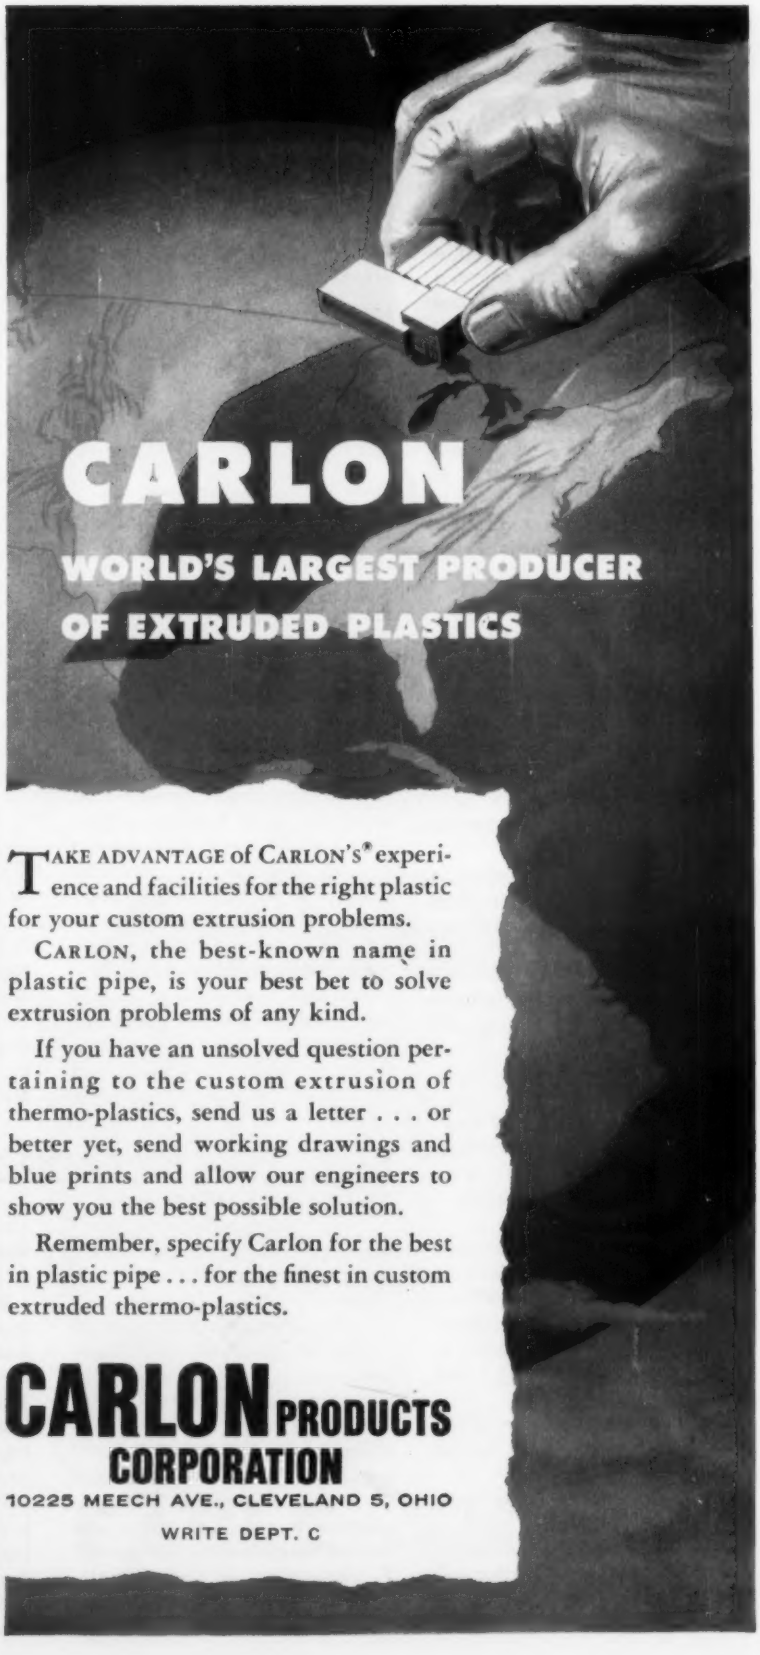
The general criteria for selecting filler materials are: they must not react with the resin, must not contain water that is readily released, and must not evolve gas under the processing conditions.

Strain-sensitive components such as toroidal coils, accelerometers, magnetic-amplifier reactors, and similar devices that are adversely affected by the mechanical compression caused by the shrinkage of a potting or encapsulation resin around them, have to be protected. The prob-

lem is to prevent asymmetrical pressures from altering the electrical characteristics of the components. If the pressures were everywhere equal, like those applied in a hydraulic system, the characteristics would seldom be affected.

One solution is to surround the device with a layer of silicone putty (for high-temperature work), or a vinyl plastigel (for ordinary applications). Another method is to wrap the core with a closed-cell, foamed-resin tape that will act as a cushion. A variation of this is to dip-coat or paint the component with a silicone or isocyanate flexible foaming resin, and allow it to foam before proceeding.

Another technique is to add flexibilizers to the resin, so that better equalization of curing stresses occurs. Thiokol rubber, polyamide curing agents, plasticizers, and other flexibilizing resin modifiers have been used.



Molds

One of the big problems in electrical potting arises from the excellent adhesive quality of the epoxies. Highly desirable in getting a solid potting job, their adhesion makes it hard to get the potted assembly free of the mold. A second problem, from the production viewpoint, is the long curing period required for development of adequate mechanical strength.

Because the epoxy potting resins are liquids, the potting must be done in molds. These molds must be pretreated with mold release agents to permit separation of the component. With a cure cycle of several hours, a large number of reusable molds would be required to get high production rates. Applying the mold release, plus loading and unloading, would involve considerable labor expense. This can result in large tooling and labor costs.

There are many ways in which these costs can be lowered. The first and best is to provide a cheap, permanent "can" or cast of metal, molded plastic, or other material for the component, that remains a part of the finished unit.

If this is undesirable, a low-

cost, waxed-paper case can be used that is stripped off after the resin has set. In cases where complex re-entrant shapes are involved, such as motor armatures and field coils, a simple vinyl mold can be made by dipping a model into a plastisol. Such molds are discarded after a few runs.

For potting objects requiring a complex, self-supporting shape, a wax, soap, or other easily worked and removable substance can be made into a prototype having the desired finished dimension. A low-melting alloy such as Cerromatrix is then sprayed onto the prototype to form a shell, and the even lower-melting wax is melted out. The component is then inserted and potted; after curing, the temperature is raised and the alloy is melted and recovered for re-use.

Mold release agents

The best surfaces for release of epoxy and polyester resins are Teflon, silicones, certain waxes and greases, and plasticized vinyl or synthetic rubber, in that order. The material selected should have adhesion to the mold, and yet no adhesion to the resin.

Silicone grease, for instance, is commonly and successfully used as an epoxy resin separation agent. However, it adheres to isocyanate resins. The diisocyanates used to make polyurethane resins are so active that they will react with almost any functional groups, even those of the silicone resins and oils. In such cases, paraffin wax, which has no functional groups at all, will give clean separations.

Techniques

The best and cheapest method of potting a component is to heat it in the prepared mold to a temperature above 220° F. to drive out moisture, allow it to cool to some lower temperature, and pour in the liquid resin.

The cure cycle should set up the resin in no less than 1 hr., and be followed by a postcure.

In cases where dense structures have to be penetrated, such as the center of fine-wire solenoids, the viscous resin may harden before it reaches the center. To speed its flow, the resin-filled mold is put into a vacuum chamber and vacuum and pressure are alternately applied until bubbling ceases.

Potted rotor for all-enclosed 100-hp. motor for acid dust service. (Photo, Epoxylite Corp.)

A special application for large-scale production requiring critical electrical and mechanical specifications in the finished part makes use of centrifugal pressure to force the resin through a fine-wire coil. The centrifuge is run hot, so that the cure can take place with the resin under pressure. This has been very successful and economical in the production of ignition coils.

For high production of components such as capacitors, resistors, transformers, and other volume items, automatic equipment can be devised. Automatic metering and mixing equipment for the resin-hardener combination is available, and plunger-type molds for automatic ejection of the finished component can be arranged on a rotary table that combines loading, filling, and curing.

There is no doubt that as labor costs increase, such automatic devices will become common, and a large number of computer and radio and television components will be so potted.

New low-cost resins with improved handling and electrical properties are gradually being made available from the petrolochemicals. This, together with automatic potting equipment, will completely change the present situation of high cost.

FLEXIBLE MOLDS FOR CASTING PLASTICS

BY EDWARD H. NEUWIRTH*

Inexpensive flexible molds for the casting of various plastics may be easily made with the polyvinyl chloride plastisols. The plastisol is a dispersion of polyvinyl chloride resin in a liquid plasticizer, along with such additives as stabilizers, pigments, and other modifying agents. Because the plastisol is a fluid, it is easily handled by pouring or pumping. When the plastisol is heated to the proper fluxing temperature, (250 to 380° F., depending on the formulation), the material fuses into a solid flexible mass.

Plastisols make it possible for engineers to use a relatively low-cost material in the manufacture of effective molds for castings. The vinyl plastisol molds are used when limited quantities of castings are needed and the initial expense would be too high for metal molds. Since plastisol molds are tough and flexible, the castings may be easily removed from the mold. This is of particular interest to molders of polyester and epoxy parts, since the adhesion

* Watson-Standard Co., 225 Galveston Ave., Pittsburgh, Pa.

Rererences were prepared by the editors.

which these materials have for metal prevents the use of metal molds.

The use of the plastisol mold with casting materials is simple. Liquid castings are poured into the vinyl mold, cured in place, and then stripped from the mold. In the case of phenolics, the filled plastisol mold is put into a 150 to 180° F. oven for proper curing. Polyesters cure at room temperature in 1 to 6 hours.

The plastisol mold may be used to cast such plastics as phenolics, furans, epoxies, polyesters, and melamines. Except when casting polyesters, approximately 50 castings may be made in the plastisol mold before breakdown of the vinyl occurs. In the case of polyesters containing styrene, only 10 to 20 castings may be made before deterioration of the mold takes place. A release agent applied to the plastisol mold prior to casting the polyesters aids in stripping the casting from the mold.

In making a vinyl plastisol mold, a positive model is first made from plastic, wood, metal, or plaster. The model is placed in a container and the liquid plastisol is poured into the container so that it completely covers the model. The container is then placed in an oven at the recommended temperature for the particular plastisol. Sufficient time is necessary to fuse the plastisol thoroughly, so that the mold will be tough and durable. Approximately 10 min. curing time at the specified temperature is needed for each ¼ in. of thickness of plastisol. After fusion of the plastisol has been effected, the mold is cooled to room temperature. The container and model are stripped from the plastisol mold, which is then ready for use.

Some typical examples of cast articles made in plastisol molds are terminal blocks for industrial control and power wiring, internal mounting for hearing aids, remote control switch handles for X-ray machines, relay connecting mounting blocks, and other types of special castings of semi-intricate designs.

EXPOSURE TESTS

"We test EVERYTHING under the sun"

All products of every size and shape, are exposed to the intense solar radiation of the world's sunniest zone exactly according to our clients' instructions. Exposure periods are measured in days or months or years, in langleys, in Ultra-violet Sun Hours, or in any other unit.

Monthly inspections and reports provide a running record of the degradation of the exposed samples.

Our exposure racks now hold thousands of samples: plastic filaments, pipes, ropes, tensile bars, chairs, awnings, tail lights, plastic-coated wires, fabrics, cables, etc., etc.

There is no better place in the world to test your product than in sunny Phoenix. For the past four years, the sun has shone for 4,088 hours per year, (over 11 hours of sunshine daily for every day of the year). On racks facing south at 45°, yearly solar radiation has totalled approximately 200,000 langleys and 2,200 UV Sun Hours.

Send us your samples! Or write for quotation and our free monthly weather report and "DESERT-ation."

PLASTISOL MOLDING

BY W. J. KAUFMAN*

A plastisol is a polyvinyl chloride resin dispersed in a liquid plasticizer along with colorants, stabilizers, and other modifying agents; the resulting compound may be either a liquid or a paste in form.

The most common molding plastisols are relatively low-viscosity liquid compounds that are pourable for ease of handling. They may be poured, pumped, or sucked into a mold, or a mold may be dipped into the liquid. They are considered as 100%-solids materials; therefore, there are no solvents or diluents to be evaporated and cause shrinkage problems. The plastisol which lines, fills, or coats the mold is converted to an elastomeric compound by raising its temperature to 350 to 400° F. Once this temperature is attained by the mass, conversion or fusion is practically instantaneous.

Vinyl sponge or foam is a recent plastisol development. Various expanded or cellular plastisols produced by different methods and having a wide range of density are now commercially available. See p. 334 for further details on the subject of the foamed vinyls.

Physical properties are determined by specific formulations

and plastisols may be compounded with properties within the following ranges:

Tensile strength	1500 to 4000 p.s.i.
Elongation	350 to 500%
Hardness (Shore Durometer)	40 to 95
Color	Clear whites, pastels, dark or bright colors
Viscosities	20 to 1000 p.

The molding techniques commonly used may be designated as 1) dip molding; 2) slush molding; 3) rotational molding; and 4) low-pressure injection molding techniques.

Dip molding

Dip molding consists of dipping an external mold into the plastisol bath, fusing or fluxing, and then stripping the finished article off the mold. Automotive pump diaphragms, spark plug covers, collapsible tubes, thread protectors, boots, and toys are but a few of the items that may be made on a commercial basis by this technique. The molds are usually solid and are made of cast or machined aluminum, machined brass, steel, or ceramic.

A typical dip molding system includes a conveyorized line passing through a preheat oven, a dipping station, a fusing oven, a cooling station, and a stripping station. The preheat oven is used to heat the mold prior to dipping. Although, in certain cases, the molds are dipped at room temperature, normally the molds are preheated to control the thickness of the plastisol deposited on the mold. For most common applications (wall thickness of 1/16 to 3/32 in.), the mold is heated to approximately 300° F. prior to dipping. For heavier wall thickness the preheat temperature should be higher. The mold is inserted into this plastisol bath rapidly and then withdrawn at a rate of from 4 to 6 in. per minute. In some cases, the mold is inverted, after withdrawal, to allow for redistribution of excess liquid plastisol. The plastisol on the mold is then fused at oven temperatures from 350 to 400° F. The length of time in the oven will vary from 5 to 15 minutes. After fusing, the mold is cooled (either

air cooled or water sprayed) and the molded piece is stripped from the mold.

Combinations of expanded vinyls and plastisol skin may be adapted to this method of molding, which is of particular interest in the manufacture of such items as boots and gloves because of the insulating qualities of expanded vinyls.

The vinyl skin is formed as outlined above. After the plastisol on the mold surface is cured, the mold is inserted into the plastisol sponge (chemically blown type) bath and then withdrawn. After that the mold is usually inverted to allow redistribution of the sponge plastisol and then fused at temperatures of 350 to 400° F.

Thickness of the sponge section may be controlled by two methods: 1) heat of the mold and 2) rate of expansion of the sponge plastisol compound.

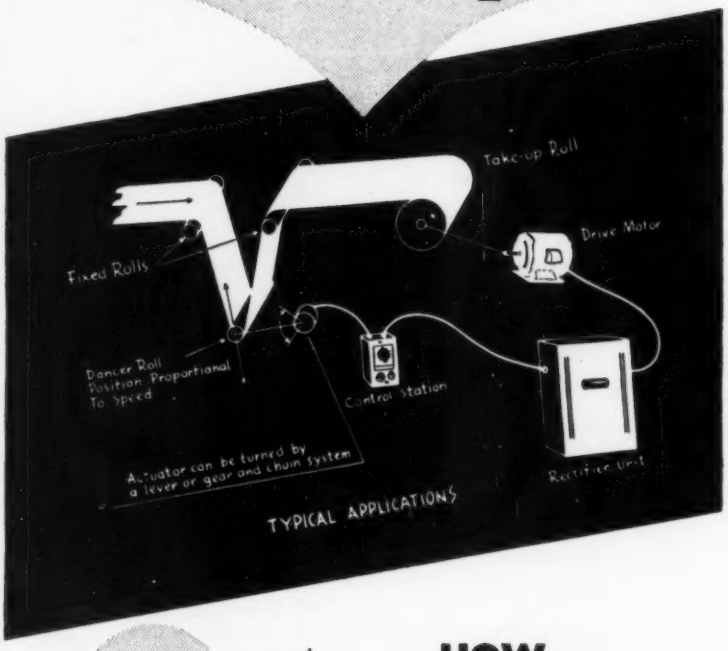
Since mold detail is on the interior of the dip molded piece, the part is sometimes turned inside out, as in the case of dip molded boots. This is usually true also of plastisol-sponge combinations since the insulation is required on the interior of the molded part.

Dip molding lends itself to high rates of production since many individual molds may be dipped at one time. This method also lends itself to practically automatic molding since the molded parts may be automatically removed or stripped from the molds by compressed air, so that a single operator may run a complete production line.

Slush molding

Basically, slush molding is a process whereby a liquid is poured into a hollow mold, then withdrawn or dumped, leaving only a lining of material on the interior of the mold. The molds used in this process are usually electroformed copper molds, or fine aluminum sand-cast molds. Heat is applied to convert the plastisol to an elastomeric compound, and then the mold is cooled to a temperature for convenient handling to strip the molded piece.

Most of the production lines us-



For the ultimate in realism, vinyl plastisol can be molded into natural foliage forms. (Photo, Marlo Studios)

ing slush molding follow one of two basic systems—the single-pour system and the double-pour system. Both of these are readily adapted to conveyorized lines.

A single-pour system involves a single filling station where the molds are filled by the vacuum, gravity, or pressure method. If gravity or pressure filling is used, the filled molds are either spun or vibrated to eliminate bubbles at the extremities. Then the molds are heated—usually by infra-red or by immersing in hot water—to adjust or control wall thickness. Heating at this point in the system is necessary so that the plastisol in immediate contact with the walls of the mold is gelled; the mold is then inverted and the plastisol allowed to drain out. The plastisol lining left in the mold is then fused in an oven at temperatures from 350 to 375° F. The fusing time depends on the size of the molded piece and the wall thickness desired in the finished part. Following the fusing cycle, the mold is cooled, usually by fine water spray.

The two-pour method is a modification of the above. Here again the mold is filled almost to the top, usually by gravity or by pumping, and the mold is vibrated to remove bubbles from extremities. It is then dumped, leaving a thin film of plastisol on the surface. By filling a cold mold in this

Servospeed
Automatic
Take-Up

HERE'S HOW IT WORKS
...for Textile and Plastics Processing

A small tension change positions the actuator shaft so as to call for motor speed change to restore preset tension. Thus a constant linear feet per minute windup may be achieved even though the radius of takeup roll increases with each turn to otherwise increase linear speed versus radius build-up. Speed is now made proportional to position of dancer roll and tension is held essentially constant, as is the linear rate of material travel.

These and other models of electronic motor speed control systems available from 1/50th to 2 horsepower.

BETTER . . . *by Design!*

VOGT Vinyl EXTRUSIONS

Custom Service . . . Fast Delivery

It's no accident that Vogt vinyl extrusions are *better* . . . they're *designed* to be! And Vogt custom service is *complete*—from the first analysis of your needs to the prompt delivery in volume of the precision-made product. Here are six reasons why Vogt extrusions will save you money:

6 Points of Superiority

1. **DESIGN** Vogt engineers will carefully design the extrusion best suited to your job.
2. **COMPOUND DEVELOPMENT** Our plastic laboratory will develop a compound to meet your most exacting requirements.
3. **COLOR MATCHING** Our color matching experts will quickly match any color or shade with the greatest accuracy.
4. **DIE CONSTRUCTION** Without delay, our die shop will construct a perfect die.
5. **SAMPLES** Our sample department will rush a sample to completion for your approval.
6. **FAST, QUALITY PRODUCTION** Our production department will make volume deliveries of uniformly high quality extrusions in record time.

Vogt's facilities include a modern research department, a complete experimental department, and experienced production and quality control departments. Thus you can be sure that the latest and most efficient materials and processes will be employed; that samples will meet your needs for color, finish, hardness, heat and light stability, volatility, flexibility, toxicity and migration; that accurate compounding, production, testing and checking will result in final extrusions that meet specifications exactly.

Whether you require tubings, rods, bindings, weltings, or special shapes, it will pay you to consult Vogt.

THIS 75-YEAR OLD FIRM SERVES THESE INDUSTRIES:
Transportation • Refrigeration • Toys • Building
Agriculture • Chemical • Furniture

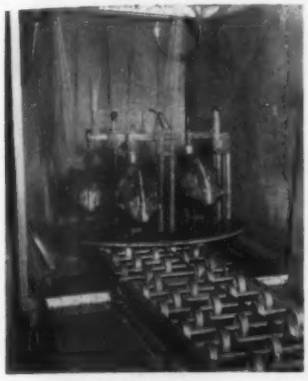
MAKERS OF VOPLEX PRODUCTS

manner there is less chance of entrapping air or of gelation over fine details at the extremities.

After dumping and draining, the mold is passed through an oven to fuse or semi-fuse the first skin. Here the oven may be either a hot-air type or an infra-red type. After passing through the first pour oven, the mold is then filled a second time, dumped, and allowed to drain. The length of time the mold is in the first oven determines the wall thickness of the final part because the heat of the mold retained from the setting or fusing of the first skin will determine the ultimate thickness of plastisol deposited on the walls of the mold. The mold is then passed through a second oven where final fusing of the plastisol part is obtained. The mold is then cooled and stripped in the same manner as in the single-pour system.

Sponge plastisol may be handled similarly when items such as boot socks and toys are manufactured completely of sponge. When a plastisol skin-sponge combination is desired, a two-pour system is used. A sponge vinyl plastisol is poured in the second position. This method is used in the production of dolls and doll parts, insulated boots, and electrical component covers.



To point out advantages of the different processes is difficult since they are very similar in nature and the final products in both methods are accepted commercially. However, it is obvious that handling in the single-pour method is at a minimum, whereas in the two-pour method the possibility of air entrapment is reduced to a minimum.

Slush molding has many advantages in the production of open hollow moldings. The process is relatively simple. Parts which show no parting line may be made in a single-piece mold. When the piece is removed from the mold t is finished and, except for decorating, there is no finishing expense. Undercuts present no problem whatsoever, as they do in other conventional types of molding. Fine detail is easily obtained.

This method of molding has

Plastisol-filled molds, mounted on metal plate are first placed in an oven for cure

Metal plate with molds then passes under streams of cold water, before removal of end-product. (Photos, McBell)

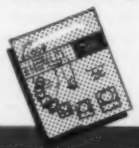
found wide usage in the doll and toy industries. Some other products made by this process are boots, finger cots, novelties, collapsible tubes, and mannequins.

Rotational molding

Rotational molding of plastisols is a modification of the slush molding technique. Rotational molding refers to the manufacture of completely enclosed hollow moldings in two-piece molds. A predetermined amount of plastisol is introduced into one half of the mold; the two mold parts are clamped together and then rotated in two planes. This rotation is accompanied by heating either to gel or to fuse the film of plastisol after it has been evenly distributed on the interior walls of the mold.

Rotational molding is rapidly replacing slush molding processes. There are several advan-

The hob (1) a replica in hard tool steel of the finished piece, is pressed into steel blanks to produce hobbed cavities (2) which are then machined (3) for insertion into a die shoe or mold frame.



CUT TOOL COSTS WITH

NEWARK DIE HOBBED CAVITIES

Die hobbing is often the key to lower tool costs. This process produces steel cavities with a minimum of machining, filing and polishing operations . . . and adds the insurance of maximum uniformity in multiple cavity molds or dies.

What's more, as the steel alternately flows and condenses under the hobbing pressure, the mold takes a closer surface grain structure that more faithfully reproduces detail in the finished product.

tages to rotational molding, namely: weight of molded parts may be accurately controlled; there is less possibility of contamination of the plastisol; the reject rate is lower; there is less scrap; and the operation is much cleaner.

Rotational molding equipment is generally classified as continuous type or batch type. Molds used for rotational molding are both electro-formed copper and cast aluminum; in some cases, machined aluminum molds are used. Depending on the surface desired on the finished product, the molding surfaces of these molds are left as they are cast or polished to a high finish. The highly finished molds produce a glossy surface on the finished product, while unpolished surfaces leave a dull or mat finish. The parting line of the molds should be machined after casting so that the mold will close tightly, preventing leakage while the plastisol is in the liquid form and thus reducing objectionable flash on the molded part.

The simplest type of rotation equipment is the batch type. Basically it consists of a platform which rotates in two dimensions simultaneously and is normally enclosed in an oven for heating the molds while they rotate. The molds are filled outside the oven and clamped on a plate. The plate to which molds are fastened is then locked in place on the rotating platform. In most cases the plastisol is fused while in the rotator; however, in some cases, the plastisol is merely gelled or set in this equipment and then removed and fused in a separate fusing oven. The advantage of fusing in a separate oven is a large turnover of molds in the rotator.

The continuous type of rotational molding equipment consists of a conveyorized system with individual rotational stations. These rotational stations travel on the conveyor. A complete cycle includes automatic volumetric filling of the molds, automatic closing, engagement of rotational gearing, fusion of the plastisol while rotating, cooling of the mold either by water spray or cooled air, automatic opening of the

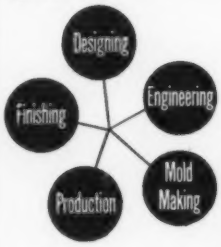
Molded plastisol one-piece housing for battery tester eliminates shortcomings of metal model at no extra cost

mold, and removal of the finished part. This equipment is highly mechanized and necessarily complicated. It is operated with a minimum of labor and is capable of achieving a high production rate.

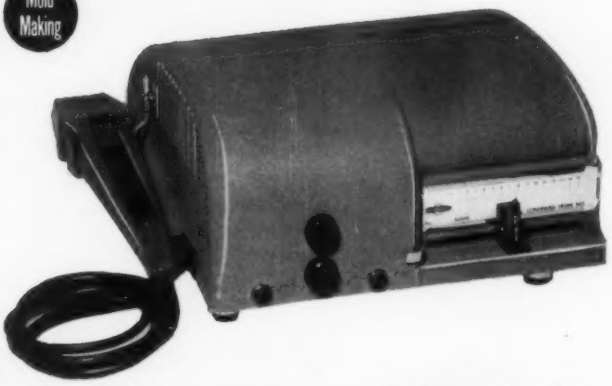
In the rotational equipment described, the rotation in each axis or plane is regular or circular in nature. By the use of irregular motion in each plane, one equipment manufacturer claims that a more even distribution of plastisol in irregular molds may be obtained.

Moreover, it is still further claimed that, by the use of cams, localized deposition may be accurately accomplished. Thus, in the case of a hydrometer bulb or a toilet tank ball valve, one section of the molded part could be of a heavy wall thickness while another portion could be much thinner.

Typical molded plastisol parts made by the rotational method are toys and doll parts, display items, balls, toilet balls, and the like.



Low-pressure injection molding



Plastisols are used in the manufacture of solid castings or solid molded parts although not as extensively as in the manufacture of hollow molded parts. The simplest process for the manufacture of solid molded parts is merely pumping or pouring plastisol into a cavity until it is filled. Usually it is necessary to use a

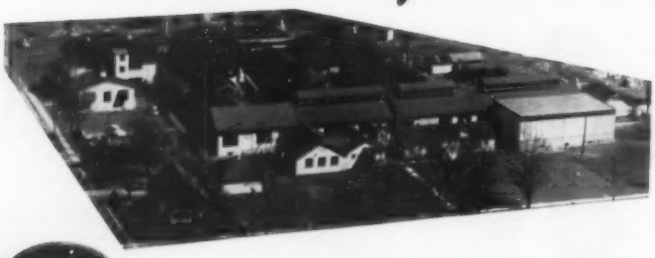
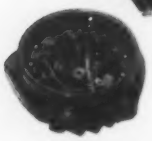
Are you a stickler for precision and quality? Then follow the lead of Peirce Dictation Systems Corp., Chicago, Illinois. Their entire operation hinges on the magnetic belt recording mechanism contained in the phenolic housing shown above. That's why they are particular about its appearance and performance. That's why they chose Industrial Molded Products to mold it.

When you call on Industrial, your compression or injection molding job is in the hands of an organization experienced in this type of work since 1934. Every operation, from mold design and manufacture to finishing and assembly, is coordinated carefully to bring you the high-quality molded parts you want, when you want them.

Multiple drilling units, such as this one shown tapping holes in a switch box, save time and cut costs for Industrial's customers. Modern mechanized assembly and finishing methods are used wherever possible. Rigid quality controls maintain established standards.





High-speed compression presses are at work 'round the clock meeting customer requirements. Industrial uses a battery of hand presses for short production or experimental runs on parts for which building expensive automatic molds is not warranted.

Write us about your molding requirements and problems . . . for fast, economical, completely satisfactory results. Industrial is known for service.

covered cavity mold for this process because during the heating or fusing cycle there is some expansion of the plastisol followed by some contraction on cooling. On parts where thick cross-sections are molded, bleeders are necessary to relieve or reduce the pressure on expansion. The time necessary to fuse any given molded part by this method will depend largely on the cross-sectional thickness of the part. A rule of thumb to determine approximate fusing time is that, for every ⅛ in. of cross-section, 7 min. of curing time should be allowed at 350 to 375° F. Molded parts with cross-sectional thickness as high as two inches have already been made and marketed.

A more advanced technique for this type of molding might be designated as low-pressure injection molding. The equipment necessary for this type of injection molding is simple since the plastisol is liquid. Low-pressure pumps of the grease-gun variety can be successfully used to inject the liquid plastisol into a two-piece mold or cavity. Here the molds must be designed with bleeders at the cavity extremities to allow for complete filling. The process is simply to close the mold, pump the plastisol into the mold until the excess emits from the bleeders, place the mold in an oven for fusion, remove, cool, open the mold, and take out the finished part.

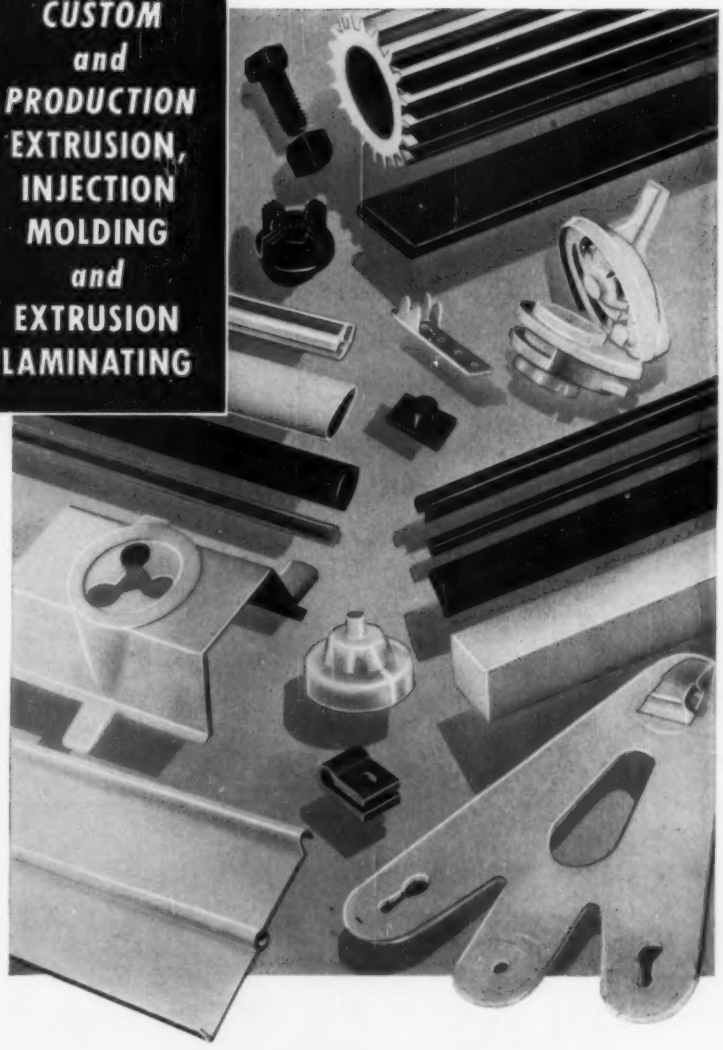
The molds used for this method are of aluminum, copper, brass, or steel, and they are either sand cast or machined. As in the rotational molds, the closing surfaces of the two-piece molds must be machined to provide a tight fit and, again, the finish of the molded part depends entirely upon the density, polish, or texture of the mold surface itself. The wall thickness of the metal molds should be kept to a minimum to provide for quick heat transmission but thick enough for good structural strength to withstand the pressures involved.

For the most part, solid plastisol moldings are made by the batch process. Conveyorized continuous molding processes are not practical, due usually to the length of time required for fusing

the solid plastisol parts. The batch process is excellent when a limited number of parts are required since the mold cost in comparison with that for conventional injection molds is very small.

Some applications of plastisol parts made by the batch process are seals for ceramic tile, sink and disposal stoppers, advertising display plaques, and novelties.

Combined methods



There are occasions, particu- parts made by the batch process vinyl combinations, when the use of two of the above-mentioned methods is advantageous to produce a single product. Items (such as arm rests, gaskets, toys, squeeze balls, and electrical packings) having a tough outer skin of vinyl plastisol and a solid interior of expanded vinyl, may be produced by spraying, slush molding, or rotational molding of the skin, and by casting, low-pressure injection, or rotational molding of the interior.

Combination plastisol skin and expanded vinyl products may be divided into two categories: 1) Those in which the complete exterior surface is a plastisol skin, as in the case of arm rests, crash pads, toy blocks, squeeze balls, toys, and others. 2) Those in which only part of the surface is a plastisol skin, such as gaskets, packing, chair seats, and others.

For products requiring an exterior surface completely covered with plastisol skin, a combination of rotational molding and low-pressure injection molding may be used. In this case the skin is molded in the normal rotational method. After curing of the skin, but while the mold is still closed, vinyl sponge or foam is injected into the interior of the mold. In the case of vinyl sponge the amount injected is predetermined, but with vinyl foam the mold is filled. Then the mold is either placed back in the rotational equipment or into a conventional oven for fusing or expanding the sponge or foam plastisol.

For products having a plastisol skin on only a portion of the exterior surface, several methods may be used. The vinyl plastisol may be sprayed on the surface

of the mold either with or without masks and then set or fused. The vinyl sponge or foam is then cast into the mold and fused. The skin plastisol may also be slushed into the mold and cured, and then the vinyl sponge or foam cast and fused.

Molds and equipment used in the manufacture of combination vinyl plastisol-expanded vinyl products are of the same general type as those used for conventional plastisol products.

The above-outlined methods are general; no two molders use the same processes or even the same equipment. Each molder has his individual ideas as to fusing time, fusing temperatures, methods of removing or eliminating bubbles, preheating of molds after fusing, etc. The suitability of the plastisol to the method and type of mold used should be determined by the individual molder, based on his own experience gained by solving similar problems in the past.

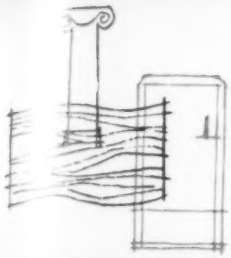
GENERAL AMERICAN

General American's capacity, versatility, service

assure the right process for your job

In plastics, you'll find General American ready to meet your every requirement. General American's *physical size* permits the setting up of special conveyors, finishing lines and equipment in their most efficient form. General American's *versatility* offers you the proper process and the correct material for your job. General American's *service* brings you experienced help with your problem. General American's research assures you of *continuing leadership* in new materials, improved techniques and product development. Because you get all these benefits from a single source, you'll find *it pays to plan with General American.*

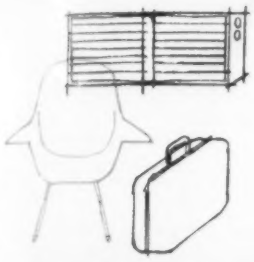
consult General American . . .



Plastics Division engineers consult with you to recommend the best method and material for producing your job. Since General American specializes in all the major molding processes you are assured of getting the correct, most economical method for your product.

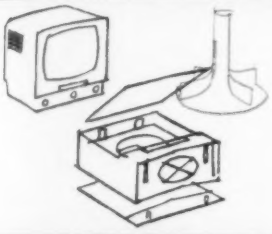
to meet your every production requirement, General American offers:

31 Compression and reinforced plastics presses ranging from 100 to 200 ton.



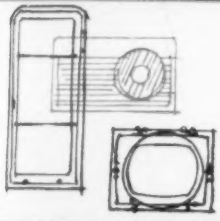
57 Injection molding presses ranging from 2 oz. to 300 oz.

7 Extruders with fully automatic in-line vacuum forming equipment



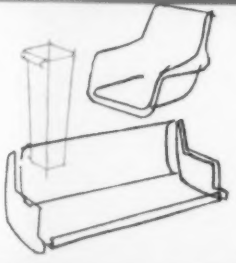
gen®

Gen, a completely new idea in decorative plastic sheeting created by General American, is an exclusive process whereby an exact photographic reproduction of any pattern, material or design can be applied on modified styrene sheeting. Simulated wood, marble, leather, etc., are easily obtained. Gen can be formed for durable, lightweight display pieces for example, or deep-drawn for refrigerator doors, automobile interiors and similar decorative applications. Gen is available in any length or width up to 40" or vacuum formed to your specifications.



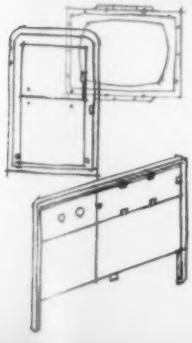
pre-mix

Where higher service temperatures and low cost are required, General American Pre-Mix may provide the answer. This is an extremely versatile molding compound consisting of the resin best suited to your application and chopped fibers such as glass, sisal, nylon or other material. Easily formed by compression, Pre-Mix requires no preformed mat and is an excellent material for plastic products or components such as radio and TV cabinets, furniture, air conditioners, carrying cases and luggage, electrical applications and automobile heating ducts or glove compartments.



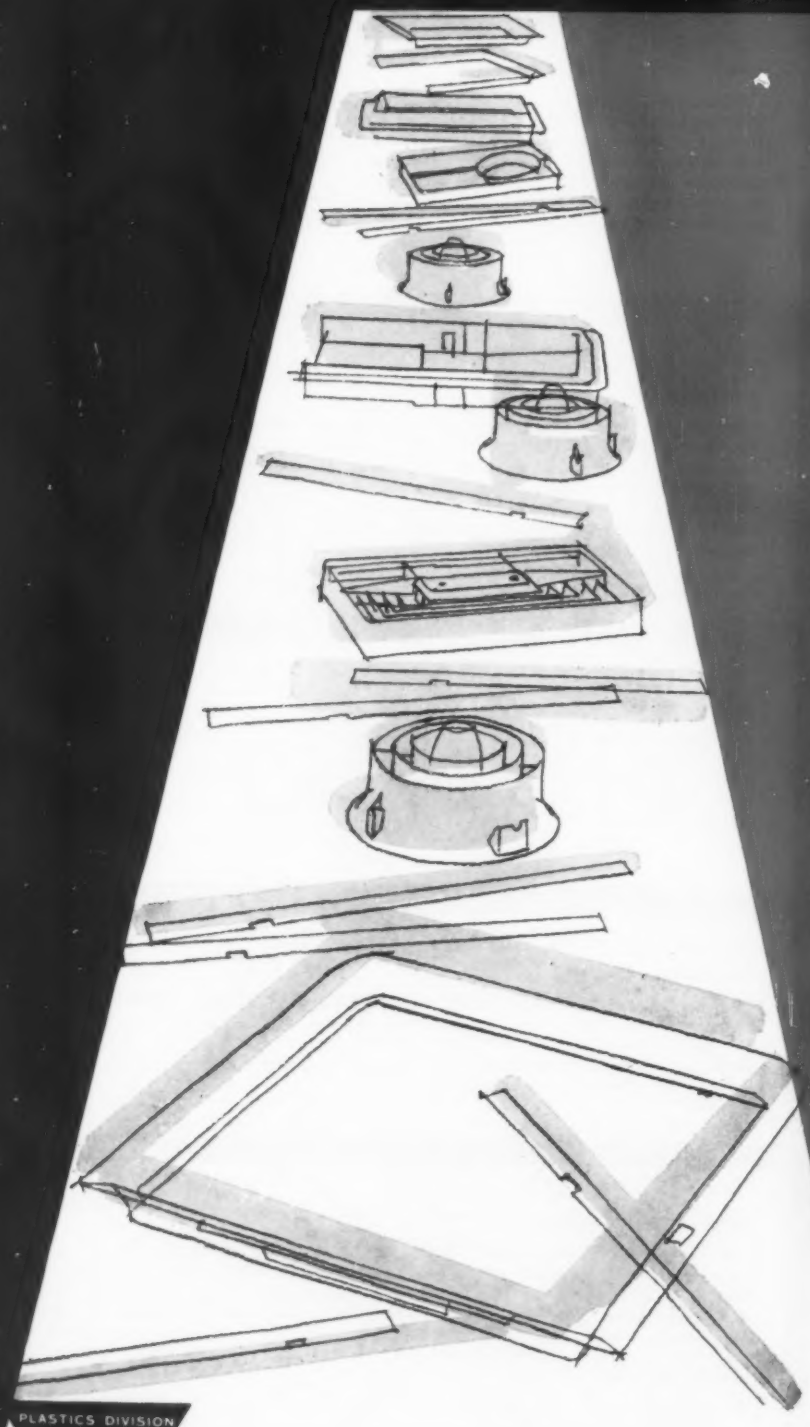
compression molding

Your product or part may require molding by compression for thermosetting plastics (melamine, urea, phenolic resins, etc.). Television and radio cabinets, electrical components and appliance parts and agitators for washing machines are some examples of the large and complex parts molded in one-shot on General American's huge compression presses.



injection molding

Injection molding of thermoplastics (the acrylics, polystyrenes, vinyls, fluorocarbons, nylon, etc.) might prove to be the best process for your part. Batteries of injection presses at General American have molded air-conditioner fronts, large refrigerator inner-door panels and breaker strips, circular fan housings and electrical appliance parts for the country's leading manufacturers.



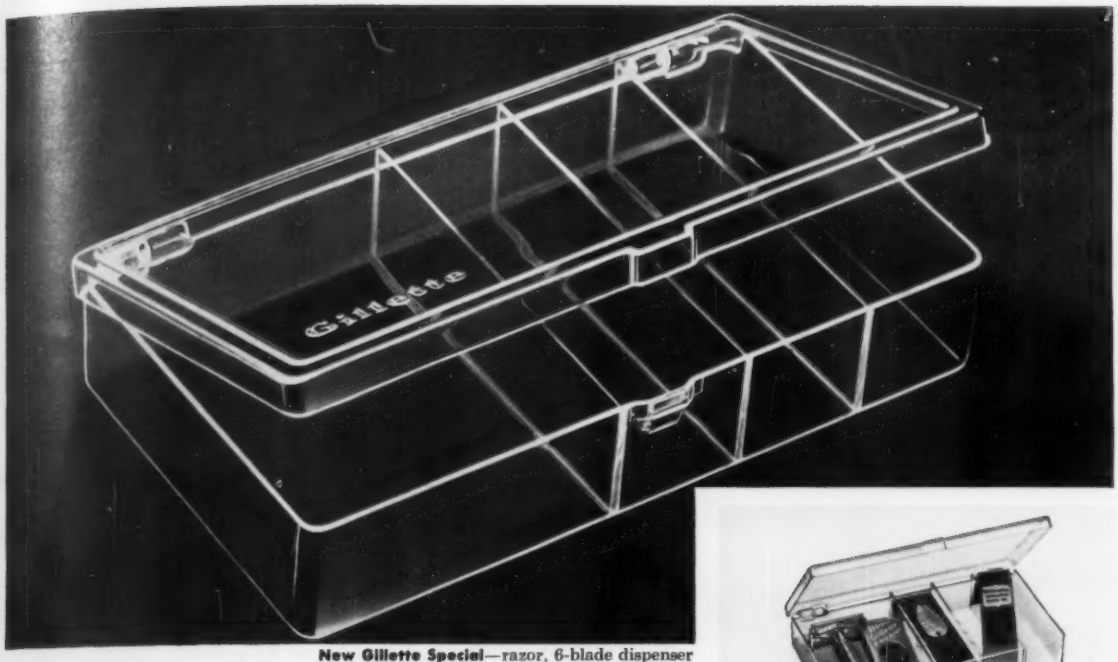
reinforced plastics

General American pioneered in the techniques of molding reinforced plastics. Using an additional substance for strength (such as glass fibers), reinforced plastics have earned recognition and acceptance because parts can be molded with great strength and light weight in large size (up to 16 feet in length on General American's new press). Sofa frames, chairs, cases, tubs, outdoor sign trims (molded in sections up to 12 feet) and office equipment housings are examples of what General American has done in reinforced plastics.

extrusion and vacuum forming

Continuous vacuum forming of extruded thermoplastic sheet has grown into an important segment of General American's plastics operation. Specially-engineered equipment for vacuum forming of high-impact polystyrene and other thermoplastics was built in the General American plant. Refrigerator panels, television-cabinet and air conditioner fronts and housings for lighting fixtures can now be produced by vacuum forming at a faster rate with advantages of ease and speed of tooling, lower cost tooling and flexibility in changing designs. Pipe for a leading manufacturer is an example of General American's custom extrusion.

it pays to plan with General American



If you are designing a new product or considering changes in a product you now manufacture, you'll find it pays to plan your products in plastics—molded by General American.

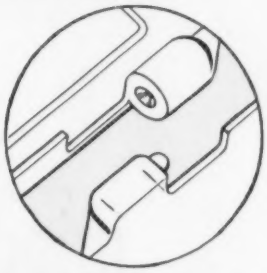
New Gillette Special—razor, 6-blade dispenser and gold-plated lure packed in a plastic box fishermen and handymen will find useful.

A Bright new idea in gift packaging by Gillette —custom molded by Sylvania



Chances are you're one of the many hundreds of thousands of fathers or fishermen to get a Gillette razor in the new plastic box gift case. If so, you've had a good close look at Sylvania injection custom molding.

You might have noticed that despite deep, thin-walled compartments, surfaces were smooth and clear and that in traditional Gillette fashion, the hinged top was securely latched but opened easily. And you probably guessed that the case was produced in high volume to meet the needs of America's gift-giving families, and Gillette shaving fathers.

A job like this calls for molding experience, facilities, and ingenuity characteristic of Sylvania. That's why manufacturers large and small take their custom-molding problems to Sylvania. Why don't you?

Write for this new brochure. It outlines Sylvania's complete custom-molding facilities, and might suggest how they can be put to work profitably for you. Write for information, too, on Sylvania's custom metal stampings; clad, plated and alloy wires; plated metal strip; custom wire welds, and special electronic components.

Snap-on hinges make it possible to mass-produce this Gillette polystyrene box in two pieces, quickly and economically snapped together to form the complete unit. Sylvania's ability to hold close hinge tolerances was an important factor in making this simplified design.

Sylvania's complete plastics services include mold making, compression, injection and transfer molding, and finishing and assembly operations.

Check with Chili

Chili Plastics is staffed and equipped to produce a wide variety of products. This measuring cup with cap and the fish-hook holder are two current examples. The hook holder—injection molded of styrene—has 20 aluminum clips set on springs, to hold the hooks snugly in place. The entire job, including the intricate assembly, was handled by Chili.

Next time you have a plastics problem, check with Chili first. You'll find that just discussing your plans with one of our representatives will be a helpful experience.

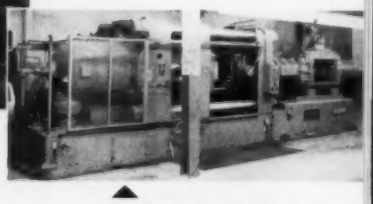
IN A HURRY ? GOT PROBLEMS NEED EXPERT HELP

Spacious new MPc plant houses design, engineering facilities . . . tool room and molding departments of exceptional capacity to assure prompt and efficient handling of the largest and smallest jobs.

COMPRESSION MOLDING

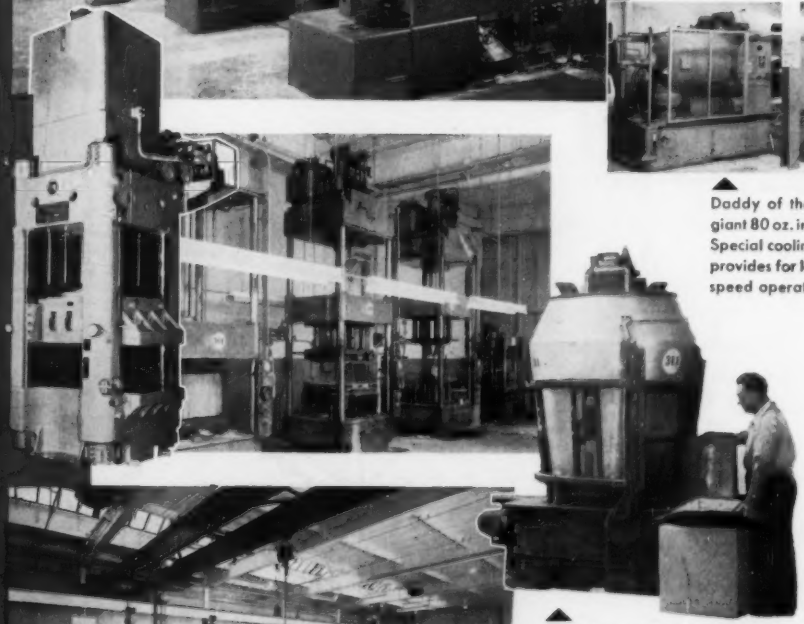
Conventional press facilities provide economical solutions for the most complex requirements. Working pressures: 20 to 3000 tons. Platen areas: 18" x 18" to 192" x 84". Maximum daylight openings: 19" to 117". Preform press capacity: 8000 lb. per hour. Advanced electronic preheating equipment.



Compression molding division includes such extraordinary equipment as this side angle press, capable of producing highly complicated parts.

INJECTION MOLDING

Battery of newest type presses ranging from 4 oz. to 80 oz. make possible efficient handling of wide variety of jobs.



Daddy of them all is this giant 80 oz. injection press. Special cooling equipment provides for low-cost high-speed operation.

REINFORCED POLYESTER MOLDING (FIBERGLASS)

Working pressures: 50 to 3000 tons. Platen areas: 18" x 16" to 192" x 84". Maximum press openings: 19" to 117".

Fiberglass reinforcements are produced by the use of modern semi-automatic preform equipment.

MOLD MAKING

The MPc tool room is equipped with the newest types of machine tools . . . such as this radial drill . . . and has a 10-ton fully motorized overhead crane for handling heavy molds.

Product designers and purchasing agents are invited to submit specifications, plastic products or problems for study and quotation.

Write Dept. W for brochure.

Premiums

• Whatever your custom needs in plastics manufacturing, call on Tupper's wide experience and modern manufacturing facilities. Our large, up-to-date plants, equipped with the best production machinery, are available for materials, injection molding, extruding, vacuum forming, blow molding—and other advanced processes.

The Tupper Engineering Department has developed the greatest number of patents in the industry for polyethylene seals, closures, and dispensers—and other items in other plastics. This know-how can be tapped by you to place your plastic products in a position of leadership.

Tupper Seals and other Tupper products are protected against unauthorized manufacture by about 150 U. S. and foreign patents and patents applied for plus numerous trademarks and copyrights.

The world's largest reinforced plastic sections enable W. R. Chance & Associates, Arlington, Va., to keep up with the boom in home swimming pools. Maraset laminating resins make the giant-scale application practicable. Epoxy production molds cost less, are made faster than metal molds. Light-weight despite their strength and size, they add to savings by easy handling and maneuverability.

Big and small production problems "float away" with Maraset resins

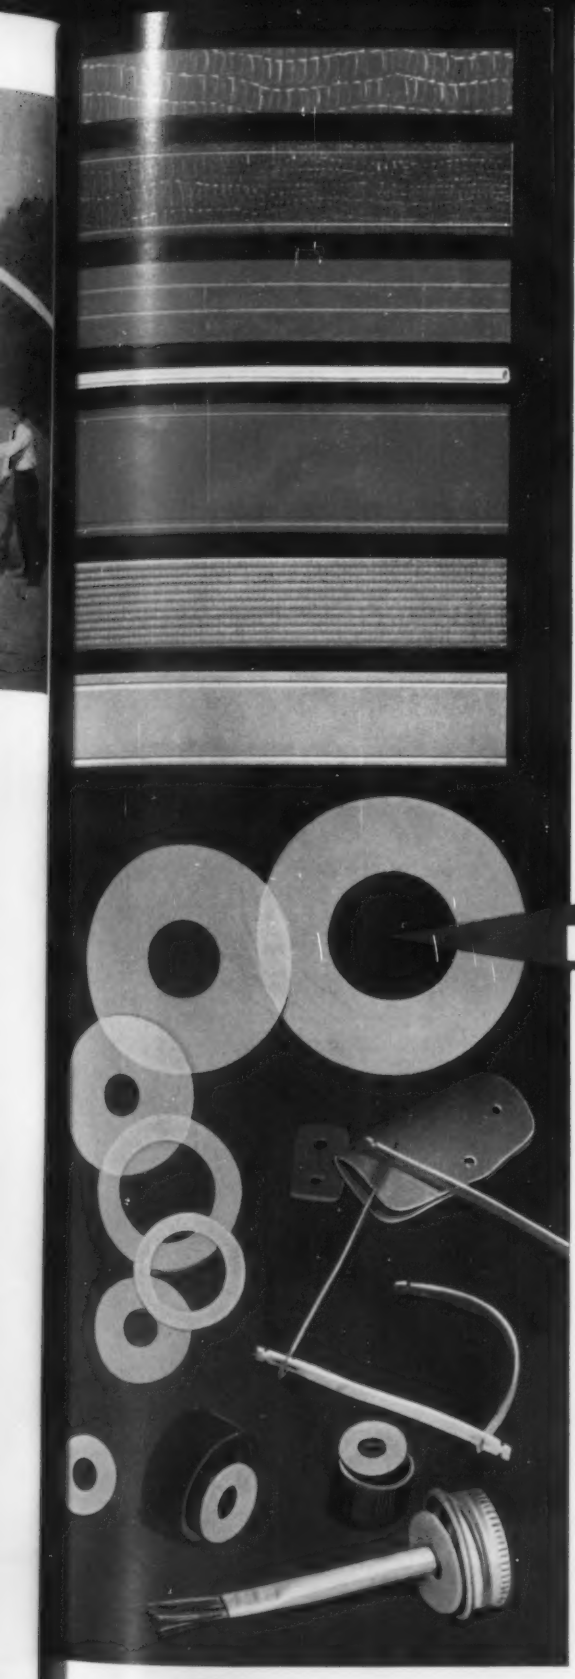
"Stay in the swim" — meet time schedules, outpace competition, develop new applications, speed up and improve manufacturing by using Maraset epoxy and Marblette phenolic resins.

Protection that aids mass production, stops delays is given by Maraset coatings to aluminum mandrels dipped repeatedly into hot liquid to make "fun balls," oxygen masks, and other thin latex products. Seamless Rubber Co., New Haven, Conn., paints the metal forms with abrasion-resistant epoxy resin that seals pores, eliminates sanding, prevents fissures that would blister and deform the rubber.

Plastic tools and dies made from standard and "specially tailored" Marblette formulations create time and labor savings as high as 80%. These versatile resins are durable, light, dimensionally stable, readily recast for design changes.

Protection for surfaces and finishes of many materials is assured by Maraset maintenance paint and varnish. These coating resins resist heat, humidity, abrasion, chemicals and corrosives.

Encapsulating and impregnating Maraset compounds offer high dielectric strength. They adhere firmly to electronic parts, cure quickly, provide a hermetic seal, guard against shock, heat, moisture, and contaminants.



FREE — new technical bulletins on Maraset resins for casting, laminating, potting, surfacing, and other uses. Practical aid based on three decades of Marblette research can help solve your production requirements.

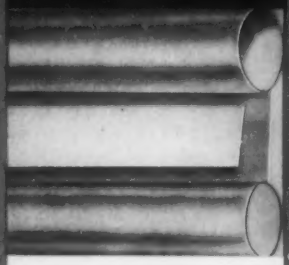
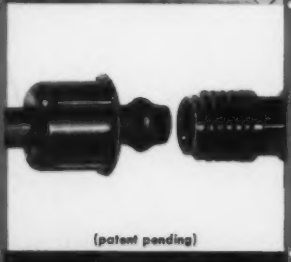
DANCO NYLON

MOLDINGS
EXTRUSIONS
NYLON TUBE FITTINGS
NYLON FILTERS



COMPLETE FACILITIES
FOR INJECTION MOLDING
EXTRUSION, MOLD MAKING

MOLDING



A pioneer in plastics, Danco produced the first commercial Nylon molding. Today—with greatly expanded facilities and experience—Danco molded parts include gears, bearings, structural members, cams, and an almost limitless number of Nylon parts for industry.

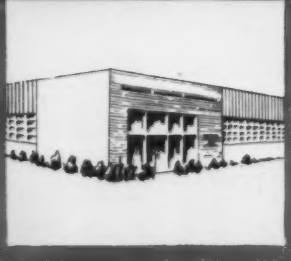
EXTRUSION

And in extrusion too, Danco has earned acclaim for its work in extruded Nylon. High-quality Danco extrusions— tape, tube, solid rod and pipe—are available in a wide variety of sizes and lengths . . . from stock or custom-made to particular production needs.

TUBE FITTINGS

(patent pending)

An entirely new concept, Danco tube fittings are especially designed for flexible tubing, both plastic and rubber. It's simple, fast, strong . . . requires NO SOLVENT . . . . NO CLAMP . . . and assures NO REDUCTION in I D. For elbows, tees, terminals, and other fittings, send your complete specifications to Danco for the finest in molded plastics.



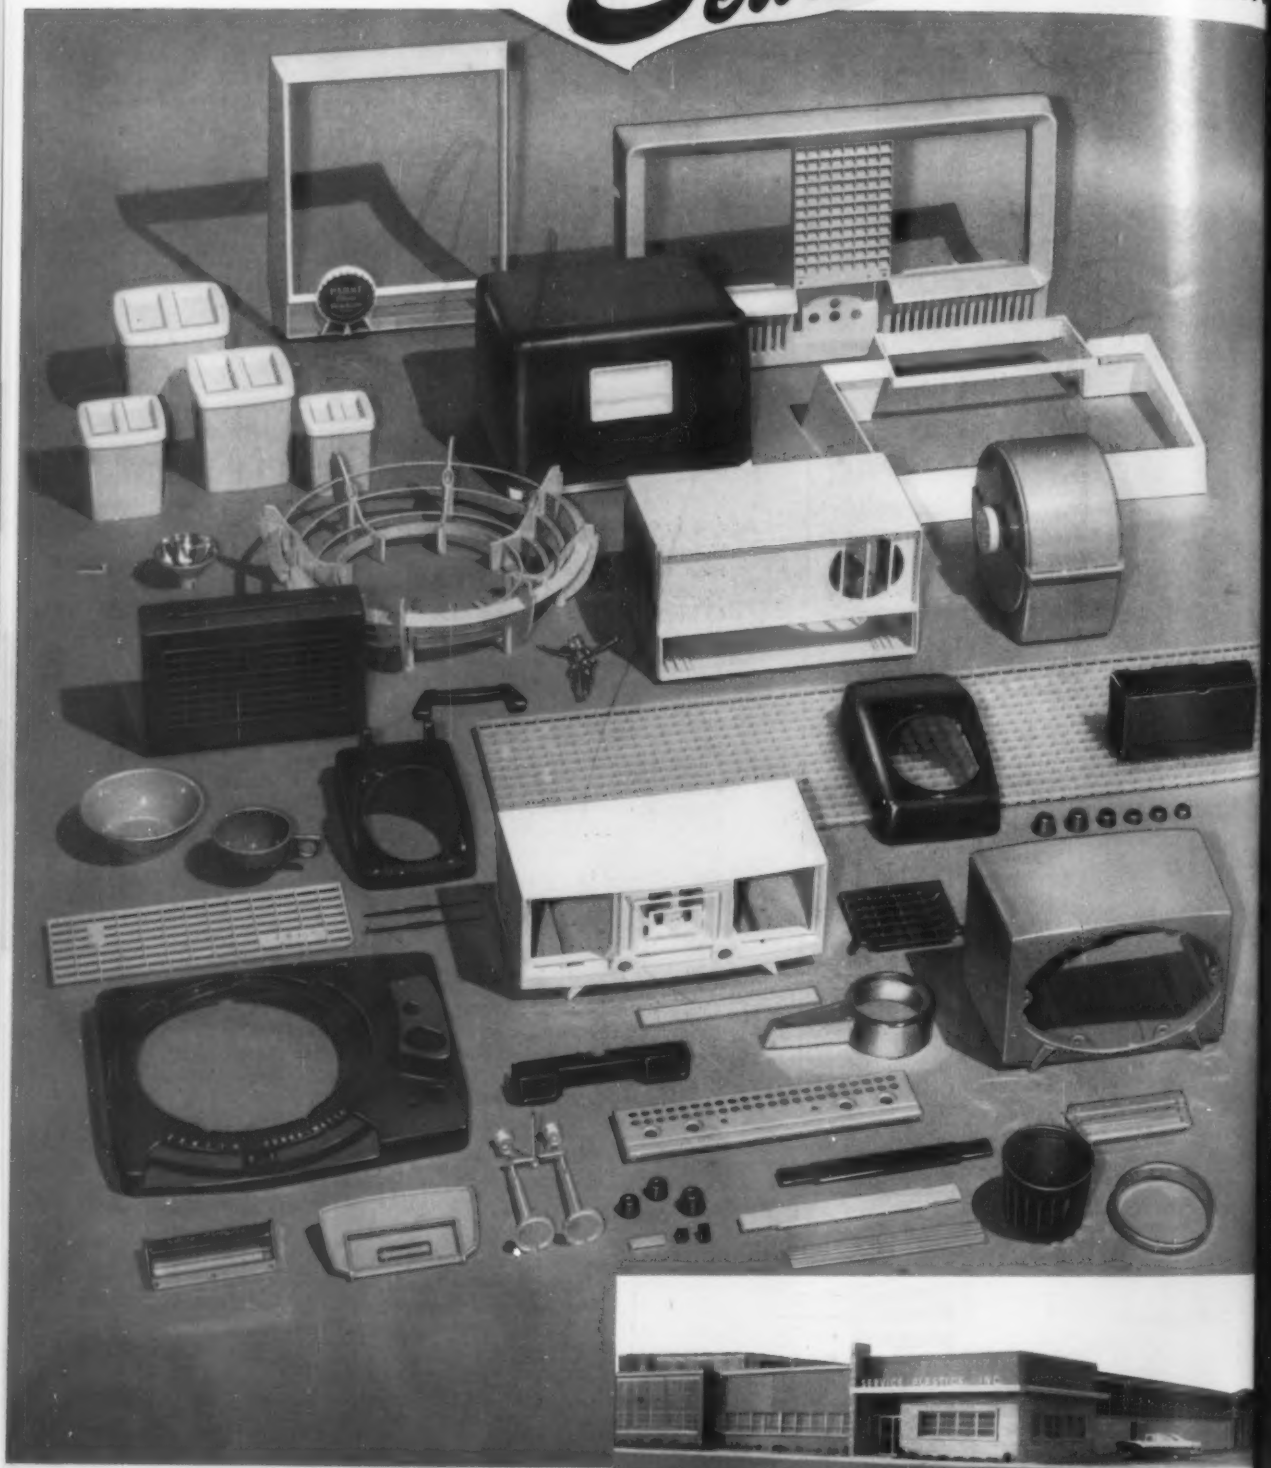
NYLON FILTERS

(patent pending)

Complete ALL-NYLON filters—with both Nylon screen and supporting structure—assure greater filtration, greater flow at lower cost. Integral screen and support, molded together in strong Nylon bond, resists corrosion and wear in hundreds of filtering applications. Ideal for filtering lube, diesel and hydraulic oils . . . water . . . gasoline . . . insecticides . . . air, etc.

NEW FACILITIES

A modern new plant doubles production area in Danielson (Connecticut). Today, Danco offers customers the combination of skilled and experienced personnel, the latest molding and extrusion machines . . . and as complete a production organization as any in the world.



Write for your copy of new informative literature on all products shown here. Or, if you have a special problem, a Danco factory-trained representative will be glad to call.

NEW **PERMAPRINT** CHECK PROTECTOR

Low Cost Check Protector

Molded in Styrene *for* APPLIED RESEARCH CORPORATION

The new "Perma Print" Check Protector, marketed by The Applied Research Corporation, prints thousands of checks without re-inking. The result is completely professional and impressive in every way

This handy check writer had to be inexpensive, lightweight, sturdy and absolutely reliable. Its cost must be low to give small retailers, professional men and even householders check protection. Quinn-Berry engineers were chosen for this job.

Here you see illustrated the many molded styrene parts and their function in the complete assembly. Precision engineering backed up by dimensionally stable thermo-plastic molding proved to be the desired answer.

Again a Quinn-Berry achievement in an unusual molded plastic application . . . proving, of course, that at Quinn-Berry the "Unusual is Routine."

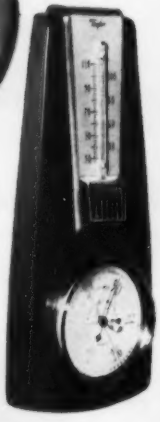
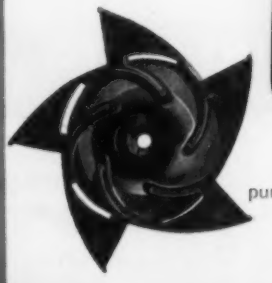
Norton is set up for more than compression and injection molding. An experienced, flexible assembly group is available for handling the operations that come *after* the plastic moldings are completed. Because of these assembly facilities we relieve many of our customers of burdensome, time consuming work. We are often called upon to assemble either parts or entire products.

Here's an example of a completely Norton assembled product. After molding the handle, Norton assembled all the units into ready-to-sell electric fry pans.



Molding—and the steps that follow, too

For more than a quarter of a century Norton has been custom molding all types of products and components for the nation's leading organizations. They have learned to rely on Norton's design service, technical skill, superior workmanship, and prompt delivery.



And these other recent jobs illustrate the varied type of moldings Norton turns out.

LEADERS IN THE FIELD OF EXTRUDED PLASTICS

CONSOLIDATED MOLDED PRODUCTS CORPORATION

SCRANTON 2, PA.

807

Mr. Bell's long distance talking machine was one of the first users of plastics in its receiver and mouthpiece.

We couldn't buy *our experience*

. . . but you can!

Founded in 1876, Auburn got into plastic molding when plastics really were new. We had a lot to learn. And we had to learn it by the good old method of trial and error. Headaches? Plenty of them! But we've been through the mill and every bit of our accumulated knowledge and know-how is at your disposal today. And we're still learning!

Whatever may be your production problem, we've probably met it — or something very like it — before. Using *every* recognized technique of plastic molding, we supply plastic molded parts to more than 400 American manufacturers, many of whose names are household words. For information on *any* phase of plastic molding, write Auburn today.

Automatic Rotary 10 automatic rotary presses can turn out millions of small parts (less than 4 sq. in.). Minimum quantities 100,000.

Transfer Molding 21 presses of 75 ton to 600 ton capacity. For fast, flash-free molding of thick or intricate phenolic pieces containing inserts.

Compression Molding 70 presses of 50 ton to 600 ton capacity.

Injection Molding 21 machines of 1 oz. to 22 oz. capacity.

Extrusion Molding Smooth, lustrous styrene sheets in any color in widths to 51", thickness to 1/16". Odd profile shapes, tubes, rods or strips in vinyl.

Tool Room Complete mold-making facilities in our own tool room make for good delivery of new molds and proper maintenance of old molds.

Today's phone, with its style, color and durability, illustrates the tremendous progress made in the plastic molding field.

PROTECT YOUR PRODUCT WITH PLASTISOL

A plastisol coating will protect your product from corrosion and abrasion and will provide a high-gloss, easily-cleaned surface. Auburn offers plastisols for coatings in a wide range of colors. Coatings that strip, coatings that can't be stripped; coatings that can be sprayed on.

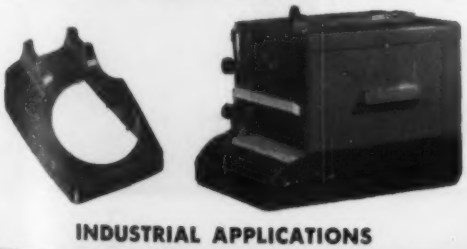
INDUSTRIAL MOLDING



EXTERNAL METALLIZING

THREE DIMENSIONAL PARTS

ERIEFLEX LENSES

INDUSTRIAL APPLICATIONS

ERIE, pioneer in custom molded plastics, has constantly maintained its leadership in the solution of difficult molding problems, in the development of new molding techniques, and in devising methods for increasing the artistic appeal of plastic products.

- **ERIE External Metallizing** gives a metallic luster to plastic, equal in attractiveness to electroplating on metal, but non-tarnishing and lasting, atmospheric resistant. In addition to the usual metal plated effects it may be had in a wide range of gleaming metallic finishes. It offers new possibilities for ornamental functional effects.

- **ERIE Three Dimensional Plastics** in sparkling, colorful, and lasting beauty, grace millions of autos, household appliances, radio and TV sets, and many other products. As identifying emblems or functional parts they are an indication of product quality and add to sales appeal.

- **ERIEFLEX Lenses** for taillights and markers are scientifically designed to concentrate the light in scintillating beams direct to approaching headlights, regardless of the angle of approach. An important safety factor in night driving.

- **ERIE Industrial Moldings** are made by the company with the longest experience in custom injection molding in the field. ERIE has produced parts which other molders said couldn't be made; and has devised economical production methods for parts which by standard procedure were prohibitively expensive.

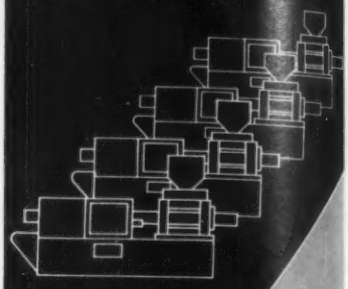
How to figure
your sales potential
in the plastics field



FREE . . . 40-page brochure will help you find answers to your questions about sales opportunities in the fast-growing plastics field.

THIS NEW STUDY contains the inside story of one of America's fastest growing industrial markets. It presents one of the most stimulating and detailed analyses of the plastics field that has yet been published. It's filled with up-to-date figures on the consumption and production of plastics materials, on the field's processing equipment requirements, on potential areas of growth. It lists hundreds of kinds of machines, accessories, chemicals and intermediates, supplies and special services for which the field is manifesting an ever-increasing appetite.

You will find this handsome brochure—file size, lavishly illustrated, 40 pages—a valuable addition to your business library. It may well point the way to increased sales for the industrial products or services that your firm supplies.

For your free copy of "The Plastics Field," simply address a note on your company letterhead to *Advertising Manager*, Modern Plastics, 575 Madison Avenue, New York 22, N.Y.

Important Facts About the $12 Billion Packaging Market . . .

PRACTICALLY ALL PRODUCTS are packaged. It's almost easier to count the industries that *don't* package than those which *do*. That's why the packaging market is horizontal . . . includes the thousands of companies that make products of all kinds that are packaged for shipment or sale.

Packaging is, in fact, so integral a part of business as a whole that it expands as business expands. In 1954, according to the U. S. Department of Commerce, the value of materials, supplies and services used in packaging the nation's output stood somewhere between 12 and 15 billion dollars. And as the national output of goods increases each year, so does the demand for packaging, packaging equipment and related supplies.

What the Market Uses . . . and Buys

The range of America's products are as wide as our ingenuity. And the variety of containers is equally broad. Depending on the nature of the product, its package can be a bag, barrel, bottle, box, can, carton, chest, crate, capsule, drum, envelope, jar, tube, vial or wrapper.

Often a package will be a composite of several of these forms and will use many materials: adhesives, coatings, cork, fabric, film, foil, glass, ink, wood, paper, plastics, tape, and wax.

To make these containers—and fill them—takes bag machines, bottling equipment, box machines, capping equipment, cartoners, conveyors, counters, die-cutters, filling machines, labelers, printing presses, scales, slitters, staplers, stitchers, unscramblers and vibrators. And they may also require such additional services as embossing, fabricating, laminating, plastic molding, and contract packaging.

All of these containers, materials, supplies, services and machines are part and parcel of "packaging." They're the factors that give the market its tremendous scope.

Who Does the Buying

The factors that control package selection are as complex as business itself. They include production, quality control, shipping, display, advertising, sales, promotion . . . and, often, outside packaging consultants. The purchase and specifications of packaging materials usually cuts across many departments of a company.

Because the buying influences are so diverse, it is difficult for salesmen to reach them all. Most suppliers, therefore, rely heavily on advertising to carry a good share of their selling lead.

How Modern Packaging Fits In

MODERN PACKAGING is the oldest and largest magazine serving the packaging field. Prior to its founding in September, 1927, the concept of packaging as a common function of many industries was not generally recognized, nor was it realized that these industries have common packaging objectives, techniques, problems and procurement needs.

MODERN PACKAGING changed all that. It gave the users of packaging everywhere a single reliable forum where mutual problems might be solved and where new packaging materials, methods and services could be publicized. As a result it gave packaging suppliers a *single* medium through which they could reach the various buying influences in the many industries that package the great bulk of the nation's goods.

Paid Circulation is Essential

Because of the intricate purchasing patterns involved in the selection and specification of package designs, materials and equipment, it's just not possible to select "packaging men" simply on the basis of job titles.

For this reason MODERN PACKAGING's policy of *paid circulation* is vitally important to advertisers. It is insurance that subscribers are directly and intimately concerned with packaging operations, because packaging men identify themselves and their interests by laying hard cash on the line.

Since the magazine's founding in 1927, its paid circulation has risen steadily—from 2,500 to its current all-time high of 20,600 out of a total print order of 24,500. The bulk of the remaining copies are used to provide additional rotating distribution for conversion into paid subscriptions.

Editorial Content

The editorial purpose of MODERN PACKAGING is to keep packagers informed of all the significant advances in the methods, materials and equipment of the art. Editorial feature space is devoted to carefully researched original articles. About 90% is staff written, 10% contributed by authorities in the field. Through the use of analyses, illustrations, case histories and "how-to-do-it" articles, the editors point out and interpret packaging trends.

Advertising Acceptance

Year after year, *more* advertisers invest *more* money in *more* space in MODERN PACKAGING than in *all other packaging publications* combined. And, last year, they set new all-time highs in both *space* and *dollar volume!*

Get More Facts

To learn more about the sales potentials in the packaging field for the products *you* make, just write to *Advertising Manager,* MODERN PACKAGING, 575 Madison Avenue, New York 22, N. Y.

To assist the user of MODERN PLASTICS ENCYCLOPEDIA in keeping track of advances in the field of fabricating and finishing, a summary on Recent Developments has been included with each of the articles in this section. All the items have been excerpted from the New Machinery and Equipment pages of MODERN PLASTICS, October 1956 through July 1957 issues.

ADHESIVE BONDING

BY IRVING SKEIST*

Pipe, vials, fabricated displays, complex toys, metallic yarn, laminated film for packaging, vinyl-clad metal for luggage—these are only a few of the plastics products for which good adhesive bonds may be required.

Through trial and error, supplemented at long last by the beginnings of a theory, the following set of rules for adhesive bonding of plastics has evolved:

1) The crystalline plastics are best bonded by heat rather than adhesives (i.e., best adhesive is the polymer itself, melted).

2) Amorphous or noncrystalline plastics are bonded to themselves with monomers or cements —either solvent cements, consisting entirely of solvents, or bodied cements, in which resins are dissolved in the solvents to thicken them, thus aiding in filling the spaces between poorly mating surfaces.

3) To bond two different plastics, or a plastic to a nonplastic, it is best to use a polymeric adhesive. For good adhesion of the two surfaces, the initial viscosity of the adhesive must be low; while for good cohesion within the adhesive layer, its final viscosity must be high. The viscosity change is accomplished by evaporation of solvents from cements, evaporation of water from latices, polymerization of monomers, or curing of resin intermediates.

4) To minimize strains (and resulting stresses) caused by flexing or temperature change, the adhesive layer should be as thin as possible, and no more rigid than the materials being joined (the adherends).

5) Solvents and polymers for adhesives should be selected to correspond to the adherends in solubility parameter. This may require the use of a two-layer adhesive if there is a big difference between the solubility parameters of the two adherends being used.

6) Low-boiling solvents give the fastest setting action, but are more likely to cause crazing. Crazing is most likely to occur with the more brittle plastics (polystyrene worst, acrylics somewhat better). To minimize crazing, avoid low-boiling solvents, or dilute them if used.

7) Plasticizer migration is sometimes a problem when two different plastics, at least one of which is plasticized, are brought

* Consultant; director, Skeist Laboratories, 89 Lincoln Rd., Newark 5, N.J.

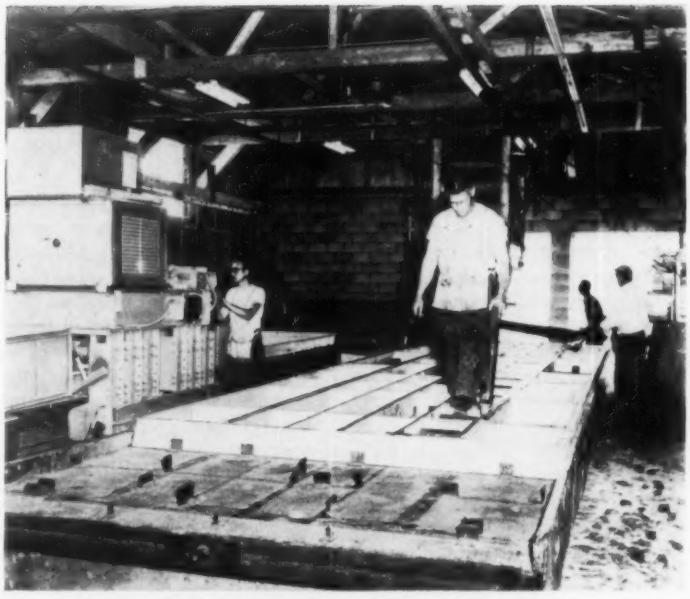
Recent Developments and References were prepared by the editors.

together. Among the remedies are: a) use of nonmigrating plasticizers, b) harder formulation of the plasticized material, c) use of plasticizers incompatible with the other plastic. The solubility parameter may aid in choosing plasticizers for a particular application.

Crystallinity and solubility parameter

These are the rules as of today. The first step in using them is to classify the materials according to ease of solubility (or noncrystallinity) and type of solvent (or solubility parameter).

In Fig. 1, p. 820, the highly crystalline, difficult - to - dissolve plastics such as 6/6 nylon, polyethylene, and Teflon[1] are at the right, while the amorphous, easily dissolved plastics such as polystyrene and polymethyl methacrylate are on the left.



The crystalline plastics are most readily bonded by heating them to a high enough temperature to destroy the crystallinity, then compositing with pressure while hot.

The noncrystalline and moderately crystalline plastics are more commonly bonded with adhesives which are liquid at the time of application but which lend themselves to the formation of a flexible solid interlayer through evaporation of volatiles or curing of a resin intermediate.

Vinyls and cellulosics are fairly crystalline and are difficultly soluble in the unplasticized state. But with the addition of plasticizer (nonvolatile solvent), they become more amorphous and consequently more amenable to adhesive bonding by volatile solvents. Also, copolymers are more easily bonded than homopolymers.

The adhesive must be chosen with an eye to solubility parameter [SP] (see References at end of article). Reading downward in Fig. 1, p. 820, the more polar plastics like nylon have high SPs while the less polar hydrocarbon and fluorocarbon plastics have low SPs. Each plastic material dissolves best in solvents whose SPs are about equal to its own. This is the modern version of the old cliché, "like dissolves like."

[1] Trademark of E. I. du Pont de Nemours & Co., Inc.

Urea formaldehyde adhesive is rolled onto the wooden frame of a trailer. Because of adhesive's strength, no nails are needed. (Photo, American Cyanamid)

Table I, p. 823, gives the solubility parameters of some of the more common solvents. There are many exceptions; but by matching this table against the chart, it is usually possible to select those solvents "most likely to succeed" for a particular plastic.

Crazing

Crazing is a problem of the more brittle plastics. If plastics are ranked according to area under the stress-strain curve, it is found that polystyrene requires the least energy to break it. That is, polystyrene is the most brittle. Next among the more common thermoplastics are the acrylics, then the vinyls and cellulosics, and finally the tough nylons.

For styrene and acrylics particularly, the choice of solvent poses a problem. The low-boiling solvents attack the plastic surfaces most quickly, permitting fastest assembly. But low-boilers also evaporate from the cemented piece most readily, leaving the joint in a state of stress which may be detrimentally relieved by crazing—the formation of many tiny cracks. Methylene chloride, highly volatile, softens polystyrene or acrylics quickly; but the polystyrene bond will craze in less than a month. Even without bonding, an injection molded piece may be sufficiently strained at the surface to craze when exposed to too active a solvent. Annealing at slightly below the softening temperature is of some help with acrylics, less effective with polystyrene.

High-boiling solvents and nonvolatile plasticizers, while slower to take hold, are safer. Perchloroethylene has been recommended for acrylics, amyl benzene for styrene. A low percentage of methylene chloride is permissible for quick starting.

Cements

Many different "cements" are used in bonding plastics. A cement may contain some resin or it may be simply a mixture of solvents. In resin-bodied cements, a single solvent is almost never used. A mixture of low- and high-boiling solvents is preferred to control the evaporation rate. If evaporation proceeds too quickly, crazing, blushing, and poor adhesion may result. If it proceeds too slowly, the cement takes too long to set.

The resin manufacturers sug-

gest the following compositions, among others, for bonding thermoplastics to themselves:

Polystyrene: Toluene, perchloroethylene, xylene, or amyl benzene, diluted cautiously with methylene chloride for speed, and bodied with 10 to 15% polystyrene if necessary.

Acrylics: Softer formulations are bonded with trichloroethane, harder acrylics with 90/10 methylene chloride/diacetone alcohol. For maximum joint strength and good weathering, it is best to soak the surfaces to be bonded in a 60/40 methylene chloride/methyl methacrylate monomer mixture which has been catalyzed by 0.2% benzoyl peroxide to cause the monomer to polymerize. Again, the cement should be bodied with a few percent polymethyl methacrylate if the surfaces are irregular, or if the acrylic plastic is to be bonded to acrylic-impregnated fabrics, as in aircraft canopy construction.

Cellulosics: Solvent cements are generally mixtures of fast driers such as acetone and slower drying materials such as methyl Cellosolve or methyl Cellosolve acetate, or even nonvolatile plasticizers. For cellulose acetate a 70/30 acetone/ethyl lactate mixture is suggested; some of the acetone may be replaced by ethyl acetate. For cellulose acetate butyrate and propionate, a 70/30 acetone/methyl Cellosolve acetate mixture is effective. The cements may be bodied with cellulose esters, or with the more strongly adhesive cellulose nitrate if the cellulose ester plastic is to be bonded to a different material.

Vinyls: The following formulations are suggested for the bonding of rigid vinyl sheet to itself. Both are based on methyl ethyl ketone (MEK), plus a small amount of acetic acid for better "bite." The first contains a small amount of high-boiler and nonvolatile plasticizer, while the second cement is bodied with a ketone-soluble vinyl chloride-acetate copolymer.

Solvent cement: 63% MEK, 20% dioxane, 10% methanol, 2.5% dioctyl phthalate, 2.5% isophorone, 2% acetic acid.

Bodied cement: 96% MEK, 2% VYNS resin, and 2% acetic acid;

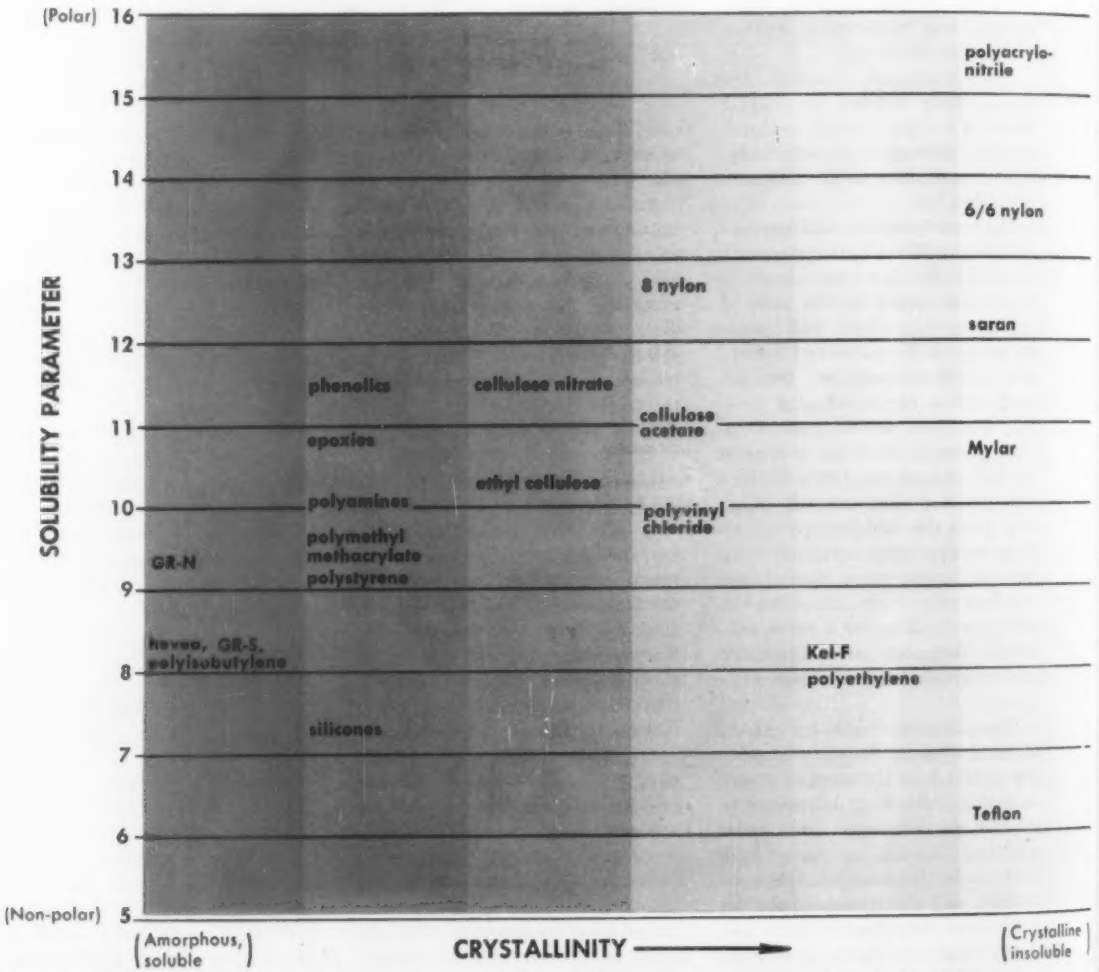


Fig. 1: Crystallinity-polarity map for the common polymers and elastomers. Crystallinity ranges from almost none at the left to half or more at the right. The more crystalline polymers are harder to dissolve, some only dissolving in hot solvents. Solubility parameter constitutes a guide to choosing an effective solvent

An epoxy adhesive kit (*Hysol Epoxy Adhesive Kit*, Houghton Labs., Inc.) contains two tubes, one of resin and the other of hardener. It is measured by squeezing equal lengths of bead of hardener and resin on a mixing surface, then mixing with a spatula. This eliminates the need for batch weighing or metering equipment. The mixed compound has a working life of 30 to 40 minutes.

A high-temperature epoxy-phenolic adhesive (*HT-424*, Bloomingdale Rubber Co.) is available as a supported film and as a liquid adhesive at 90% solids. It produces high strength in large-area metal-to-metal bonds.

A low-viscosity epoxide adhesive (*Eccobond 55*, Emerson & Cuming, Inc.) for joining metal, glass, ceramics, and plastics, and for crack filling can be cured at room temperature.

A modified urea formaldehyde resin liquid adhesive (*Formica Urea 185*, Formica Corp.) is formulated to give craze-resistant glue lines up to 0.02 in. thick. This material may be cold- or hot-set at temperatures from 70 to 180° F. It can be used with hydraulic presses, screw-type presses, or hand clamps. This adhesive provides highly moisture-resistant bonds meeting the requirements of Federal Specification CG-496, Type III.

A pressure-sensitive film adhesive (*Tackmaster*, Rubber and Asbestos Corp.) is a formulated polyvinyl ether composition with outstanding retention of original adhesion values even after prolonged exposure to heat, oxidation, and light. The adhesive film is sold in roll form with a release paper on one side.

A fast-setting contact adhesive (*Hybond 56*, Pierce & Stevens Chemical Corp.) is recommended for most types of dissimilar lamination involving plastics laminates, fiberboards, leathers, wood, etc. The adhesive is said to produce an odorless, nonstaining bond with high dead-load strength but sufficient elasticity to resist shock and fatigues.

A new water-base adhesive (*Chemigum Latex Based Adhesive*, Bond Adhesives Co.), which permits lamination and assembly of certain diverse materials previously not practical, has butadiene - acrylonitrile copolymer (*Chemigum Latex*, Goodyear Chemical Div.) as its chief ingredient. It is a nonflammable-type adhesive with exceptional resistance to humidity. Clarity and flexibility are other characteristics of the material. This adhesive is efficient for bonding polyurethane foam.

Two adhesive products (Compo Chemical Co.) are expected to stimulate the prefinished metal markets. One, a primer, is said to improve plastisol- and organosol-metal bonds which permit all tooling operations. The other, a cement, adheres semirigid vinyl to a wide range of metal and other materials; it is claimed that the resulting bonds can be broken only by tearing the vinyl. The laminate can be deep-drawn, punched, cut, drilled, or crimped with no separation of the plies.

A new contact adhesive (*C-9199*, Pierce & Stevens Chemical Corp.), an elastomeric compound of modified neoprene base, permanently bonds decorative laminates, honeycomb paper, metals, and wood. Bonds are odorless, nonstaining, and resistant to heat, moisture, oil, grease, and many chemicals.

Three new adhesives (National Adhesives Div., National Starch Products, Inc.) for laminating may be applied by reverse roll or gravure methods. A rubber-based adhesive (*Resyn 36-6254*) is designed for laminating cellulose acetate butyrate to foil in the production of metallic yarn. A vinyl lacquer adhesive (*Resyn 76-3930*) is intended for laminating reverse-printed cellulose acetate to foil used in "boilable" flexible containers. The third adhesive (*Resyn 76-3944*) is for laminating polyester film (Mylar) to metalized polyester film, or polyester film to foil.

A new adhesive (*Resyn 76-3963*, National Adhesive Div., National Starch Products, Inc.) will bond rubber hydrochloride (Pliofilm), saran, and polystyrene to foil, rubber hydrochloride to saran, and polyester film (Mylar) to rubber hydrochloride or saran. The synthetic rubber cement contains approximately 33% solids and may be thinned with toluene, or mixtures of toluene with methyl ethyl ketone or ethyl acetate.

Pressure-sensitive transfer film (*Double-Face*, Angier Adhesives Div., Interchemical Corp.) for instant adhesion is adaptable to a variety of porous and nonporous materials and conforms with ease to highly irregular surfaces. The pliable film, incorporating a special tissue reinforcement, is supported by a double-coated release paper which can be removed at once for instant bonding, or at a later date by the consumer. The film is suggested as a substitute for liquid adhesives as well as for mechanical fastenings.

Three resin-base, multi-purpose adhesives (*Tygobond 40, 41*, and *45*, U.S. Stoneware Co., Adhesive Div. 1) have been developed to bond vinyl foam and sponge to themselves or to vinyl fabrics, metal, wood, or composition bases. These air-drying, fast-tack type adhesives are crystal clear and nonstaining. One (*Tygobond 40*) is for spray applications; the others are easily applied by brush or machine coating.

A new line of industrial adhesives (*Ray-Bond*, Raybestos-Manhattan, Inc.), including both thermosetting and thermoplastic compounds, can be used for bonding, coating, or sealing plastics, wood, metal, glass, ceramics, friction material compounds, leather, paper, insulation materials, rubber, and cork.

Three-layer packets for food, cosmetics, drug products, etc. are laminated with bodied cement. (Photo, Celanese Corp. of America)

the strength develops as the solvent evaporates over a number of hours.

Bonding of dissimilar plastics

Adhesive bonding is often the only practical method of bonding dissimilar plastics, but the bond is usually weaker than that obtainable by bonding together two separate pieces of the same type of material.

The main obstacles to be overcome are the difference in solubility parameter, and plasticizer migration. To take care of SP differences, the adhesive should cover a wide SP range. This means it should be one of the amorphous materials at the left in Fig. 1, p. 820. Nitrocellulose dopes are effective for cementing together cellulose acetate and cellulose acetate butyrate. Buna-N rubber, the butadiene-acrylonitrile copolymer, sometimes blended with vinyl chloride copolymer, is utilized for bonding the vinyls.

Plasticizer migration may occur when one of the adherends is a plasticized vinyl or a cellulosic. It may cause crazing when the other adherend is polystyrene or polymethyl methacrylate. The most obvious remedy is to use a harder formula of the plasticized component. Sometimes it is feasible to switch to a closely related material which requires less plasticizer: from PVC to the chloride/acetate copolymer, or from cellulose acetate to either cellulose propionate or cellulose acetate butyrate.

In vinyls, the higher-molecular-weight, straight-chain polymeric plasticizers are nonmigrating. The preferred plasticizers for both vinyls and cellulosics, when they are to be in contact with polystyrene or acrylics, will be those having the higher SPs since they are less likely to emigrate to the lower SP resins.

Bonding thermosets

The thermoset resins are inherently good adhesives in their intermediate, partially cured, still-plastic condition. When fully cured, they are resistant to solvents and cannot be bonded by solvent cements. Generally, they can be bonded by more of the same: phenolics by phenolics, etc. But the epoxy resins will bond phenolics or polyesters to themselves even more strongly than the phenolics or polyesters themselves. In the case of glass-reinforced polyesters, the superior adhesion of epoxy resins to glass is an additional reason for employing adhesives based on epoxy resins.

In addition to epoxies, alloys of phenolic with Buna-N, or phenolic with polyvinyl butyral, are effective for bonding phenolics to themselves as well as other materials. The alloys are softer, better able to resist stresses than straight phenolic.

Plastics to other materials

Plastics are often bonded to metals, glass, paper, cloth—polar materials with high solubility

Synthetic resins facilitate the bonding together of separately molded styrene parts for housewares items. (Photo, Dow Chemical Co.)

TABLE I: Solubility parameters (SP) of solvents and resins (S=soluble)

Solvent	*Drying rate*	*SP of solvent*	*Polystyrene (SP=9.1)*	*Polymethyl methacrylate (SP=9.5)*	*Vinyl chloride polymers (SP=9.7)*	*Cellulose acetate (SP=10.9)*

Nitromethane	fast	12.7				S
Ethyl alcohol	fast	12.7				
Water	medium	23.4				

parameters. Fortunately, many polymeric adhesives are available which contain hydroxyl groups or other high-SP groups capable of adhering to these polar surfaces. Among them are proteins, starches and dextrins, gums, polyvinyl alcohol (actually a copolymer with acetate), polyvinyl butyral, cellulose nitrate, vinyl chloride copolymers with maleic anhydride, amino resins, phenolics, epoxies, and others. Those that are most diverse in makeup, such as the epoxies and polyvinyl butyral, are most likely to succeed in bonding plastics to nonplastics.

Composite adhesives, in which metal is primed with a phenolic, for example, and then coated with vinyl, are in use both here and in England.

In thin laminates, bond strength is less important than flexibility and ease of application. Envelopes for drugs, coffee, etc., can be made of adhesive-bonded laminated film. The outer layer of the envelope, reverse-printed on the inside surface, is cellulose acetate. Laminated to the acetate is a layer of 0.0007-in. aluminum foil. Bonding may be accomplished with vinyl acetate or chloride copolymers, cellulose nitrate, or Buna-N rubber, in a mixture of solvents of marginal solubility parameter for cellulose acetate, e.g., toluene and isopropyl acetate. Inside, the foil is thinly coated with vinyl for heat-sealing. The package is strong, attractive, and impermeable to water, oil, and gases.

Adhesive layer requirements

Aside from covering the solubility span, the adhesive layer must fulfil certain rheological requirements.

When applied, it must have a low viscosity in order to spread and to wet and adhere to the surfaces. But for good cohesion in the cemented part, the adhesive layer must soon increase in viscosity or even be cross-linked. Several routes are available to reach these conflicting demands on viscosity. These are outlined as follows:

1) Solutions (dopes, cements) of polymer in organic solvents. These give good bonding; and the characteristics of the final bond, after all solvent has been removed, are predetermined by the known properties of the polymer base. Unless at least one of the adherends is porous, all the solvent must be evaporated after the adhesive is spread on and before the surfaces to be bonded are joined together, since negligible solvent will be absorbed by the adherends. In such cases tackifiers may have to be added to the cement to get good adhesion of the evaporated coated surfaces, and there is the possibility that they may reduce the unit strength of the finished bond.

2) Polymer latices. These are suspensions of polymers or elastomers in water. They are often the cheapest and most convenient to use, but the bond is not as strong as that yielded by other methods. As with cements, if both adherends are impervious to water, the water must be completely evaporated before the surfaces are pressed together.

3) Polymerizable monomers, such as methyl methacrylate. These are slower-setting than the other materials, but have the advantage that no volatile substance needs to be removed from them in the manufacturing process.

4) Curable-resin intermediates, such as urea formaldehyde, phenol formaldehyde, melamine formaldehyde, epoxy, isocyanate,

unsaturated polyester. This is the fastest-growing group, especially the epoxies, because of their adaptability to a wide variety of applications.

There will always be strain when an adhesive-bonded sandwich is flexed or subjected to temperature change. If the coefficient of thermal expansion of the adhesive is markedly different from that of the adherends, heating and cooling will cause shear stresses at the interfaces. If the adhesive is stiffer than the adherends, stresses will accumulate at the interfaces upon flexing, and failure may result. For this reason, the adhesive layer should be thin and somewhat less rigid than the adherends.

MACHINING THERMOPLASTICS

BY GEORGE CARLYON*

Virtually all the thermoplastics can be satisfactorily machined, using the same type of setup as is used for such soft metals as yellow brass, provided allowance is made for plastics' greater sensitivity to heat.

Thermoplastics are also poorer conductors of heat than are metals, and so suffer from a greater buildup of heat during the machining process. At the same time, they have a much greater thermal expansion rate. Finally, being thermoplastic, they soften or distort at temperatures well below those which may be generated by machining.

When these factors are ignored in the machining of thermoplastics, gumming or tearing of the plastic, or binding and sticking of the tool may result. Excessive strains may also be introduced in the piece which is being machined.

General recommendations

Generally, these results can be prevented by: 1) the use of coolants wherever possible; 2) the use of a tool design which gives adequate clearance; and 3) the operation of tools at relatively high speeds and at a slow rate of feed.

The following recommendations apply, *in general*, to all thermoplastics and all machining operations.

Coolants: A water-soluble cutting oil or compressed air jet—which also clear chips out of the cut—make the best coolants for cutting tools. Other liquid coolants may contain chemicals which could attack thermoplastics. A 10% solution of oil and water is probably best for most applications.

Tool design: In most cases, tools should be set with a zero or slight negative rake, and should have a scraping rather than a cutting action. This tool design facilitates the clearance of chips. At the same time, it minimizes a tendency of the more resilient plastics, such as the fluorocarbons, to flex away from the tool during turning operations. Tools should be kept sharp, clean, and free of nicks and burrs to prevent chipping and to minimize frictional heat.

Because of their high rate of heat buildup, plastics are often harder on tools than metals several times as hard. Wherever production runs will justify, carbide-tipped tools are recommended. They have a much longer life between sharpenings, produce a cleaner cut, and can be operated at higher speeds. For most ordinary machining operations, high-speed steel tools specially designed for use with plastics are also available.

Tool operation: Tools should be run at as high a rate of speed as practical. Experience will determine the proper rate. Before starting production runs on any unfamiliar plastic, a few sample parts should be made. A smooth, continuous flow of ribbon-type shavings is evidence of good procedure. The tool is operating too fast or otherwise overheating if it produces scorched, stringy, or web-like chips.

The feed should be uniform and moderate. If the feed is uneven the piece may become marked. Attempts to remove too much material at one cut will result in chipping, chattering, or other damage to the piece. On turning

Recent Developments and References were prepared by the editors.

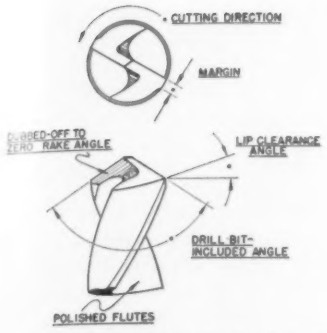

Fig. 1: Schematic drawing of drill used for thermoplastics. (Sketch, Rohm & Haas Co.)

operations, a light finishing cut will produce a smooth, semimatte finish, requiring little or no polishing for most applications.

When close tolerances are required, thermoplastic parts should be inspected at a standard temperature (usually 72° F.). The part should be stress-relieved at critical stages in the machining process. Since the piece may expand considerably during prolonged machining, allowance must be made for the subsequent contraction on cooling. It is wise to make the final sizing cuts after the piece has cooled completely to room temperature.

Specific recommendations

Acrylics and *nylon* machine very well—better than many metals. Properly annealed parts have been made to tolerances of ± 0.0005 inch.

Nylon is highly water-absorbent. When close tolerances are required, it is boiled in water before machining until it has a moisture content equal to that which it will have when it is in service.

Fluorocarbons and *polyethylene* also machine well but require more care to hold close tolerances because of their exceptionally high rate of thermal expansion and their flexibility. For turning operations on these plastics, enough stock must be left for an adequate cut, or the tool may simply slide over the piece, elastically compressing it without cutting it.

In their most common gages—up to ⅛-in. in many cases—*acetate, vinyl, high-impact styrene, fluorocarbons, polyethylene,* and *nylon* may be punched, blanked, or sheared to size.

General-purpose *polystyrene* is highly brittle and must be worked with a coolant and slow feeds. Annealing is definitely desirable.

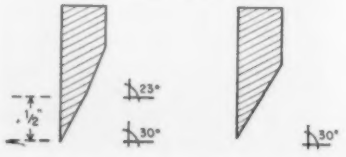
Sawing

Most of the saws used for cutting metals may be used for plastics. Where the economics of production do not justify carbide-tipped blades, high-speed steel blades designed especially for the cutting of plastics are available. Steel blades should be hollow-ground. Carbide blades, particularly for circular saws, are recommended with "square and advance" teeth, designed so that alternate teeth start and finish the cut. A coolant is not needed in most cases with carbide tools.

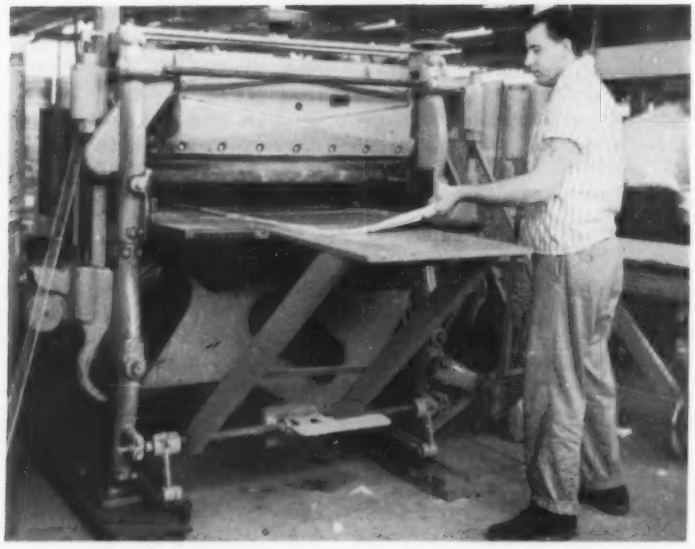
Circular saws produce best results on long, straight cuts or thick material. To minimize chipping, the saw blade should project above the table just a little higher than the material's thickness.

A *panel saw,* or traveling circular saw, produces best results on stacks of several sheets or single sheets over 2 or 3 ft. long, on sheets with vulnerable surfaces (such as unmasked acrylic), or on trimming of irregular edges. The saw is moved by hand crank or

RECENT DEVELOPMENTS



Beside-the-press grinders (*Models 3X* and *3XX*) of the new foremost grinders have extra-large throats and are especially designed for grinding scrap molded parts as well as trimmings from thermoformed sheet. The *3X* has a throat opening of 10 by 16 in. and is powered by a 5-hp. motor, while the *3XX* has a throat opening of 10 by 24 in. and has two 5-hp. motors. *The Rainville Co., 224 Seventh St., Garden City, N. Y.*



The "Flying Cutter" is a circular saw that has virtually no dip or gullet between its teeth. The carbide teeth are welded into the rim of the saw blade in such a way that they protrude slightly above the circumference. This construction, it is claimed, eliminates grabbing and saw-cut flash. It is satisfactory for thin plastic extrusions that cannot be cleanly cut with conventional saws. Ten to thirty times as many cuts can be made between sharpenings as with conventional blades. *Lemmon and Snoap, Grand Rapids 4, Mich.*

A roller-type die cutter will cut parts from continuous roll stock up to 72 in. in width. The roll stock is fed between power-driven pinch rolls that pull a predetermined length of stock from the supply roll. The loose stock trips a switch that moves the cutter roll to the rear of the machine while two other pinch rolls pull the stock onto the cutter bed over the dies. The cutting roll then traverses the bed, making the cuts. *Falls Engineering & Machine Co., 1734 Front St., Cuyahoga Falls, Ohio.*

A new drill for sheet plastics (*Roto-Bor*) is a different approach to the problem of cutting holes in a thin sheet, something difficult to do with standard drills. It consists of two rotating points centered on a shaft having a pointed retracting positioning tip. Mounted in any drill press or hand drill, it cuts through the sheet around the circumference of the circle only, in somewhat the fashion of a hole saw. Result is a clean cut and an accurate, chip-free hole. *Jancy Engineering Co., 508 S. Pine St., Davenport, Iowa.*

Fig. 2: Recommended cutting edges to be used on resilient, rigid thermoplastics materials. (Drawing, Bakelite)

Heavy flexible vinyl sheet can be sheared to size with sharp-edged steel rule dies at room temperature. Rigid vinyl should be heated before shearing

power along guide rails above the work, while the sheets remain stationary, usually under a hold-down bar.

Band saws are used to cut curves in flat sheets or for rough trims of formed parts. Though not as accurate as circular saws for straight cuts, they can be used on short cuts and run cooler than circular saws.

Special band saws, known as skip-tooth or buttress saws, have been developed especially for plastics and soft metals. They have coarse teeth and extra-wide gullets to give clearance to the large plastic chips.

For most plastics the higher the speed in ft./min. of blade travel the better the resulting cut will be.

Jig saws may be used to cut closed holes or small radii in thin stock, whenever other methods are not practical. Blade tooth clearance should be sufficient.

Routers

Routers are used to shape curved sections or to cut formed parts to size. Smooth cuts can be obtained by using straight, two-flute cutters at high spindle speeds and slow-to-moderate feeds. When portable routers are used for cutting, the sheet or part should be clamped to a table. If many identical pieces are to be cut, a templet can be used both as the bearing surface and guide for router.

Drilling

Twist drills specially designed for thermoplastics are readily available. These provide maximum clearance for the cutting edges. They have a zero or negative rake angle, and extra-wide highly-polished flutes and lands. A drill design with much longer flute leads than are conventionally used will permit the attainment of higher production speeds.

The work should be securely held and a slow, careful feed used when "breaking through" to avoid chipping.

In deep holes, the feed should be slowed, and drills should be backed out frequently, to clear the chips and avoid excessive heat buildup.

Compressed air can be used as a coolant for holes of moderate depth. Water-soluble oil can also be readily squirted into the hole by means of plunger-operated oil cans. A pilot hole may be drilled and filled with a wax stick. The wax acts as a lubricant and supports and expels the chips. In transparent plastics, this method produces smoother and more transparent holes.

In deeper holes, a jet or oil-hole drill will feed soluble oil coolant directly to the proper point.

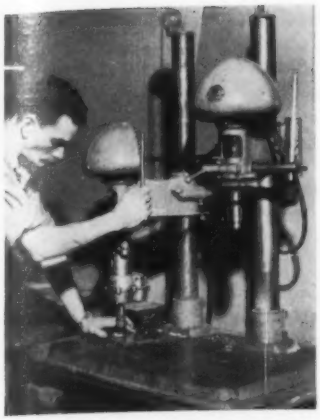
Large-diameter holes can be cut with *hollow end mills*, *fly cutters*, or *hole saws*, or they can be bored.

Turning, threading, tapping

Standard machines can be used for most thermoplastic turning and threading operations. Tools should have a zero-to-slight negative rake and should be kept as sharp as possible to insure clean cuts. Threads can also be die-cut. Alignment of the work and die must be perfect to obtain best results.

In turning the resilient plastics such as nylon which produce a continuous chip that may wrap around the work, a chip breaker can be ground on the tool to overcome the problem.

Taps for thermoplastics should have a slight negative rake and should produce threads with slightly rounded grooves. This gives better clearance of chips and avoids cracking at the root of the thread. Standard taps and dies for copper and brass may be used, if thus modified.



A special tap has been designed for plastics and soft materials. It has two flutes and two cutting edges, instead of the usual four, to facilitate chip removal.

National series coarse threads should be used wherever it is found to be possible.

Taps should be backed out pe-

Threads are easily turned on cast acrylic rod. Tools used should generally have a zero-to-slight negative rake

Taps for use on thin acrylic sheets should be backed out periodically to clear the threads of chips and to avoid stripping

riodically to clear the threads of chips and avoid stripping. Lubricants should always be used. In some cases, a wax stick inserted into the drill hole prior to tapping will serve as an adequate lubricant and also serve to expel chips. In clear plastics, this also produces a cleaner, more transparent thread.

Shearing, blanking, punching

In relatively thin sheets, most thermoplastics can be sheared, blanked, or punched to size with sharp-edged steel rule dies more economically (in quantity) than they can be sawed or drilled. Standard hand or power presses or slitters can also be used.

Small nonprecision parts can be punched out in a single operation. High speeds are possible with well-made dies. Steel rule dies may be operated in presses similar to those used in the printing industry, the rubber or leather industry, or in standard metal punch presses.

For large production quantities, closer tolerances, and/or the heavier-gage materials, all-steel dies operated in standard metal punch presses would be the proper

Blanking, even in heavy thicknesses, is highly economical when intricately shaped parts are to be formed and dimensional tolerances are not too close.

Shearing or blanking of thin sheets in stocks is not recommended with most plastic materials because the sheets tend to adhere at the edges.

Specific recommendations for cutting plastics sheets are as follows:

Acetate, butyrate, flexible vinyl, and polyethylene, in thicknesses up to ⅛-in., may be cut at normal room temperatures by many means, including simple hand snips. Acetate patterns may be scored with a sharp knife and then snapped out of the sheet. This is often used to make intricate templets.

Rigid vinyl, above 0.015 in. in thickness, should be heated to about 160° F. before blanking or shearing.

High-impact styrene can be cut cold with blanking dies in many cases. Where intricate shapes are to be cut, it is advisable to heat to 160° F.

Nonprecision parts of *nylon* up to ⅛ in. and *fluorocarbon* or *polyethylene* parts up to ¼ in. can be punched or blanked cold from sheet or strip in many cases. If cracking occurs in nylon or fluorocarbons, it can be overcome by preheating the strip or soaking it in water.

Punching and shearing of regular *polystyrenes* has not been found practical in most cases. However, oriented polystyrene sheeting can be punched and sheared readily.

Grinding

Thermoplastic rods can be production sized by centerless grinding to tolerances as close as ±0.0005 inch. A silicon carbide wheel with an open grain is used in a water jet. Abrasive wheels are not normally used for cutting, as they tend to burn the stock.

Finishing

After fabrication, most articles require some form of finishing to remove tool marks and restore natural luster to the material. Care in the final machining cut will minimize the amount of finishing required.

The friction of buffing, sanding, or polishing too long or too vigorously in any one spot can generate enough heat to burn or soften a thermoplastic surface. The part should be kept constantly in motion relative to the wheel to keep heat buildup to a minimum. The direction of buffing should be changed often. Machine sanders for finish work should be run with coolant.

Filing: A "Vixen" file, such as is used on aluminum and other soft metals, with deep, single-cut coarse teeth, is effective in working thermoplastics. Files designed specifically for plastics materials are also available.

Sanding: Where sanding is indicated, a coarse wet or dry sandpaper is used, followed by successively finer grits until a satin finish is obtained. Wet sanding is usually most desirable.

Ashing and buffing: Ashing is a semifinishing operation on a cotton or muslin wheel with a slurry or paste of fine pumice and water. It will remove most light scratches and saw marks without prior sanding. The part should be washed after ashing or buffing to remove excess compound.

Finish wheels: Following ashing, buffing with Tripoli or a chrome-coloring compound, followed by a soft loose wheel on which no abrasive is used, will give a high luster. For the final operation, a coat of wax, preferably antistatic, is sometimes applied. This is preferred for many applications because of its water-resistance and nonattraction to dirt or dust particles.

Solvent polishing: Acetates, bu-

Large holes are blanked into high-impact styrene sheet with steel dies. The 10-gage sheet can be worked cold without any damage to the sheet

tyrates, and the acrylics are sometimes polished by immersing the parts for a few seconds in acetone, butyl acetate, ethylene di-chloride or other proper solvents, or by exposing them to the solvent vapor in a vapor chamber. The solvent reacts with the surface of the plastic and forms a film which dries to a high gloss.

Acetate or *butyrate* articles may also be wiped with a cloth which has been dipped into a solution of 95% isopropyl alcohol and 5% methyl Cellosolve acetate. The cloth should be saturated afresh before wiping each piece.

Because of the volatility of most solvents, adequate ventilation must be provided to eliminate inhalation of the harmful vapors, and precautions taken to avoid fire or explosion.

Acrylic parts which have been solvent-polished or flame-polished should be thoroughly annealed at maximum temperature to prevent crazing.

Flame polishing can be used for the polishing of acrylics, particularly for slots and inaccessible areas. An oxy-hydrogen flame is used, with nozzle held about 4 to 6 in. from the stock and moved along slowly (about 4 in./sec.). Too slow a speed will overheat and may result in slight bubbling of the surface; a second application of the flame—after the material has cooled—will usually restore the surface.

Acetylene flames should not be used as they tend to deposit carbon on the surface being polished and on adjacent areas.

DECORATING MOLDED PLASTICS

BY LLOYD E. PARKS*

While painting is the last in a long series of steps in producing decorated plastics parts, quality and ease of decoration are dependent on all previous operations. Agreement through compromise must be reached between the artist and the engineer, both making such changes as are necessary to produce quality parts practically and economically.

Design and molding

Plastics parts must be molded relatively free of stresses to avoid unnecessary crazing or cracking in use. Stresses may be introduced when parts are machined, flexed, shocked by impact, or subjected to abrupt and uneven changes in temperature or the action of certain solvents. Crazing results in distinct surface cracks or minute frostlike internal cracks when stresses exceed the tensile strength of the plastics. If when local stresses are present but are less than the tensile strength of the plastic, the part is under strain and may appear perfectly sound but may crack or craze at a later time if additional stresses, sufficient to exceed the tensile strength, are introduced. Quality parts must be molded relatively strain-free and this is particularly important if they are to be decorated by painting (1).[1]

If parts are to be decorated on the second surface, assembly lugs, reinforcing ribs, metal inserts, knockout pins, and sprues must be located with care since they may show through the clear plastic and spoil the effect. If parts are to be spray painted in more than one color, edges and corners must be sufficiently sharp to insure close fitting of spray masks. Narrow deep grooves and small holes must be sprayed at a very small angle which tends to fill the bottom of the groove or hole without coating the side. Paint tends to pull away from small raised angles, making them more difficult to spray than large angles or areas which have rounded surfaces.

If a part is to be silk screened, the area must be flat or at least smoothly curved. If letters are to be filled by the spray and wipe method, they must be sufficiently deep to avoid wiping the wet paint from the indentation.

If parts are to be decorated completely or in part by hot stamping, the method of hot stamping should be determined in advance and the part designed for the operation.

Annealing

Even with the best of design and molding techniques, many parts must be annealed to avoid rejects on the paint line. Some molders anneal all plastic parts; others anneal only those that cannot be molded sufficiently free of strain for decorating. In the case of the latter, the decision to anneal comes after all attempts to adjust paint solvents and molding cycles fail to produce parts satisfactory for decorating.

The most satisfactory method of annealing is to apply heat at a relatively low temperature for a long period of time. Polystyrene is commonly annealed at approximately 140° F. for 4 to 8 hr., depending on the type and size of the part. Acrylic parts may be annealed at 135 to 160° F. for varying lengths of time depending on the type of part and the type of acrylic plastic. Parts of either acrylic or polystyrene may be taken directly from the press and dipped into hot water for annealing. Seven to 10 min. at 140 to 180° F. should be sufficient for most parts. However, the precise temperature and time cycle must be worked out separately for each part.

There is a chance of warping parts in the annealing operation and in some cases it is necessary to clamp them in a jig to maintain shape.

When annealing in a water bath, it is common practice to use a small amount of detergent to promote wetting of the part and rapid draining as parts are removed from the bath. Such wetting agents may also serve to reduce static electricity on the part

Designs **of genuine sterling silver, gold, or gleaming nickel** can now be applied directly to black or colored plastics materials. The metal is applied electrolytically and is guaranteed not to chip or rub off under normal use and care. *G.M.C. Process Corp., New York, N. Y.*

Rubber-faced design rollers for flexographic printing of continuous over-all designs are now available as lightweight, slip-on "D-Mount" sleeves. Made of a light-metal alloy, the sleeves are designed to fit interchangeably on a special shaft built to insure very close tolerances. Disassembly is simple, permitting rolls to be stored while the shaft is in use with another roll. The rubber printing surface is molded to the customer's design and vulcanized to the metal backing. Available for single- and multi-color designs in face sizes up to 90 in. and diameters up to 9 inches. *Mosstype Roller Co., Inc., Waldwick, N. J.*

The Kensol 60 roll-leaf stamping press applies permanent, fine-quality trademarks, decorations, directions, etc., on almost any kind of plastics, including thermosets. It will mark both flat and high (up to 5.5 in.) items and has a wide range of pressures obtained by using two air cylinders in the imprinter drive. (One can be inactivated when making light imprints.) Dwell is electrically timed. Head and roll-leaf attachments come in two sizes: 6 by 8 and 8 by 12 in., with larger sizes available on special order. A 6- or 12-station turntable attachment is one of several feeders available. *Olsenmark Corp., 124-132 White Street, New York 13, N. Y.*

A flocking machine weighing only 80 lb. features, aside from its compactness, a tilting supply hopper that makes it easy to empty unused flock or to change quickly from one color to another. The machine has only two moving parts: a sparkproof blower and a long-stroke magnetic-vibrator feed mechanism that is built into the feed hopper. The feeder is wired so that it cannot operate unless the blower is running, thus preventing overloading and clogging of the blower. Once-a-year cleaning is sufficient for both the totally enclosed motor and the feeder. The unit is used in conjunction with an adhesive spray gun: the operator can spray adhesive with one hand and apply flock with the other. *Progressive Equipment Co. (PECO), 8625 Mackinaw, Grand River, Detroit 4, Mich.*

In this combined spray booth, spray painter, and mask washer, parts to be sprayed are fitted into workholders—which may also act as masks—and mounted on the machine spindle. As many as four guns spray paint on the spinning part. Speed of rotation ranges from 40 to 400 r.p.m. and the pedal-activated guns stop automatically at the end of a timed period. One mask is automatically washed in an agitated solvent bath while the alternate is being sprayed. This procedure is safer for the operator and less likely to damage fine wire bridging on masks. *Conforming Matrix Corp., 364 Toledo Factories Bldg., Toledo 2, Ohio.*

---

and thus reduce the amount of dust collected between annealing and decorating. Such wetting agents should be selected with extreme care, since they remain on the part and may adversely affect paint adhesion.

Cleaning the part

It is desirable that plastics parts be designed so they can be molded relatively strain-free without the use of mold lubricant. Mold release lubricants interfere with paint adhesion and must be removed (Fig. 1, p. 830). Moderate amounts of stearate lubricant may be removed with solvents which do not attack the plastic surface. Silicones are more difficult to remove with solvents. The Dow Chemical Co. (2) recommends a solution of 4 oz. of Oakite No. 24 in 1 gal. of water for removing silicone lubricant. A 20-min. immersion of the molded part in the solution at 145° F. is recommended, followed by a water rinse. This solution will also remove stearates and other contaminants.

Parts should also be dust-free for decorating. It is helpful to dip the parts in an antistatic solution immediately after molding to reduce the amount of dust contamination between molding and painting. Antistatic agents which do not adversely affect the paint adhesion must be chosen.

Some parts are wiped just before painting to remove dust and other contamination.

Paints used

Plastics differ in physical and chemical properties, and these differences affect the type of paint required. It is, therefore, important to select a paint specifically for the plastic to be decorated.

In the plastics industry the term "paint" is used broadly to cover both lacquers and enamels (3). Lacquers are particularly desirable for use on thermoplastic surfaces since the film hardens without baking. This eliminates the possibility of heat shrinkage and warpage of molded parts. Also, parts rejected because of blotches or errors in painting can usually be reclaimed quite easily by removing the paint with a combination of paint solvents inactive toward the plastic. Enamels harden by solvent evaporation and subsequent oxidation or polymerization or both. Enamels may be considered as thermosetting and are particularly useful for thermosetting plastics such as phenolic, polyester, urea, and melamine where reasonably high baking temperatures can be tolerated without damage to the plastic part.

Colors: Plastics parts are deco-

Fig. 1: Mold release lubricants interfered with paint adhesion in the piece on the left. The numerals are depressed into the second surface, painted in a light color, and viewed through the plastic. The white areas indicate where the paint "bridged," or pulled away from the corners in the bottom of the numerals. It is necessary that lubricants be removed before painting

rated to make them look better; in most cases the paint serves no other purpose. Accordingly, color is most important. To facilitate production color matching and color control, it is recommended that designers use a reasonable number of pigments, no more than three or four at the most, in arriving at colors. It is most important to work with single pigment colors in blending at the design stage. It is a mistake to blend three or four matched colors, each of which may contain three or four pigments and expect an exact or even an approximate match in production.

Preparation for use: Paints are mixtures and in all cases it is necessary to stir well before using to assure uniformity. Unless careful study is given to selecting an alternate, the recommended thinner should always be used. Adhesion, gloss, humidity blush resistance, cratering orange peel, etching (Fig. 2, p. 831), crazing, dry time, and stability of the paint system may depend on the thinner.

Control: In setting up a decorating job it is important that paints be evaluated thoroughly and specified to meet the requirements of the appplication. Such points as grease resistance, humidity resistance, stain resistance, light resistance, heat resistance (Fig. 3, p. 832), abrasion resistance, gloss, adhesion, viscosity, and percent solids should be checked. Once the decorating job is under way, it is impractical to check all these points on each incoming batch of paint. Such control is unnecessary since it is improbable that basic errors in formulation will occur that cannot be detected by less extensive routine control.

However, each batch should be thoroughly mixed and checked for color. If special thinners or retarders are used to correct problems in production, the color should be watched to catch any irregularities that might arise from improper compounding.

Production parts should be checked by visual inspection and a spot check should be made for adhesion. Many companies have accepted transparent Scotch tape #600 and masking tape #202 (Minnesota Mining and Manufacturing Co.) as the standard materials for the adhesion test.

Methods and equipment

In decorating molded parts, color is added by spraying, silk screening, dipping, rolling, or hot stamping. Basically these are the same methods used for years in decorating other surfaces (4, 5).

Spray coating: Spray coating is widely used for decorating all types and sizes of plastics parts. The method is particularly adaptable for painting large areas and uneven surfaces and for the application of multiple colors by the use of spray masks. Spray coating is quite economical as a decorating method and productivity is high in well-equipped paint shops.

Suction feed guns and reasonably small suction cups are commonly used in spraying small areas and parts in short runs. Uniformity of the paint film depends on careful adjustment of paint viscosity, air pressure, and upon the gun opening.

Pressure feed tanks are used almost exclusively for spraying large areas or in long runs requiring a large volume of paint. The tank is connected directly to a conventional hand or automatic spray gun by a fluid hose and the paint is forced from the tank to the gun by air pressure. Since pressure feed tanks are stationary in operation they should be equipped with air agitators to keep the paint well mixed. This is particularly important in the spraying of paints in which particles such as pearl essence and metallic powders have been suspended.

Uniformity of spray application is particularly important in spraying metallic and pigmented metallic finishes. If one panel is sprayed extremely dry and another extremely wet, the colors may differ appreciably due to the difference in the degree of flooding of the powder. If sprayed dry, the film may be almost immobile when it hits the plastic, thus allowing very little flooding or orienting of the powder. If the film is extremely wet, the powder may flood excessively, giving a quite different color. (Fig. 4, p. 833.)

For spray application, paint is usually thinned to a standard viscosity suitable for the particular job. It must be thinned sufficiently to spray, yet the resulting film must be viscous enough to hang on corners and edges when the paint hits the part. This is accomplished by use of a low boiling solvent which evaporates between the spray nozzle and the plastic surface, allowing for an increase in viscosity in the paint before it hits the surface. Extra high boiling, high boiling, and much of the intermediate boiling

solvents strike the plastic part with the paint as it is sprayed and control the properties of the wet paint film. Groups of solvents are classified in Table 1, below.

Spray masks

Parts may be decorated with several colors by a series of successive spray operations using a series of electroformed metal masks that shield certain areas while other areas are painted. Basically there are three types of masks. The *lip mask* may be used for spraying depressed designs, in which case it is form-fitted to the area around the depression with lips extending down the side walls of the depression. A variation of the lip mask is used for shielding raised or embossed designs while the surrounding area is painted. Here again a lip extends down the side walls. Usually it is desirable to have two colors meet on these vertical walls rather than at the surface edge of the area being masked. The *plug mask* fits snugly in a depressed area to protect it while the surrounding area is being sprayed. It does not have a lip. The *block mask* confines paint to the general area of a small design or group of designs and is commonly used in filling operations where excess paint must be removed by wiping.

Electroformed lip and plug masks must fit accurately for good work and this usually means a different set of masks for each mold cavity. Accordingly, it is highly desirable to have masks fitted to good production parts. Masks should be handled with reasonable care in operation and should be held snugly to the parts while the paint is being applied. A poor fit will allow paint to blow by with a resultant clean-up cost on a sloppily decorated part.

Precision masks may be held in place by hand and gravity. However, there are many air clamping devices available for holding them in contact with plastics parts for decoration.

The book-type lip mask in Fig. 5, p. 833, is used for painting the wide dark stripe around the center and the narrow dark stripe around the top of the model bus body. The part is located on a nesting block and again the mask is closed by a pedal-operated air clamping type arrangement.

Masks of several different types may be required to decorate one part.

Paint accumulates on masks as successive parts are sprayed and must be removed at regular intervals for good production. The number of parts that can be sprayed before the mask is washed will depend on the job and to a certain extent on paint formulation. However, under the best conditions, masks must be cleaned quite often. This may be done with a solvent such as acetone and a hand-brush operation or with one of various types of automatic mask washers.

Screen process printing

The general subject of screen process printing has been covered in detail by Kosloff (6) and most of the general technology is useful in decorating plastics.

The process is used extensively for printing both flat and curved surfaces on a wide variety of molded parts. It is particularly adaptable for multi-color decorating by successive screening operations with a series of different screens. It is more economical than spraying for decorating elaborate designs.

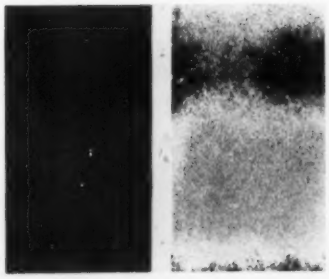

Fig. 2: Since metalizing accentuates defects, proper lacquer base coat must be applied before metalizing to get good finish (left) (brightness shows as black); improperly thinned coat causes defects (right)

The basic equipment used in screen process printing is the screen, commonly called the "silk screen," regardless of the fabric used in its construction, and the squeegee which is used to force paint through the design in the screen to the part being printed.

The screen consists of a taut woven fabric securely attached to a rectangular wooden framework and carefully masked with a stencil in a manner that will allow paint to be pressed through the fabric only at areas where the stencil is open.

Woven silk, nylon, copper, stainless steel, and many other materials are used in making blank screens. Nylon has replaced silk and is perhaps the material most commonly used in screens for printing molded plastics parts.

The mesh of fabrics used in screens for such work usually varies from 125 to 150. However, screens are commonly classified by the number classification of the fabric used. By this system, numbers 12, 14, and 16 screens are most common. As the number increases, the mesh of the screen becomes finer, with a resultant thinner film of paint on the printed part. Thin films give better detail but may result in poor hiding.

Design printing: For design printing, a stencil must be added

TABLE I: Classification of paint solvents

Low boilers	*Intermediate boilers*	*High boilers*	*Extra high boilers*
Methanol	Isopropyl alcohol	Amyl acetate	Cellosolve acetate
Ethyl acetate	Sec-butyl acetate	Butyl acetate	Butyl Cellosolve
Isopropyl acetate	Methyl Cellosolve	Butanol	Butyl lactate
Acetone	Methyl isobutyl ketone	Diisobutyl ketone	Methyl carbitol
Methyl ethyl ketone	Toluene	Xylene	SC-150
Hexane	VM & P naphtha	SC-100	
Heptane		Methyl Cellosolve acetate	

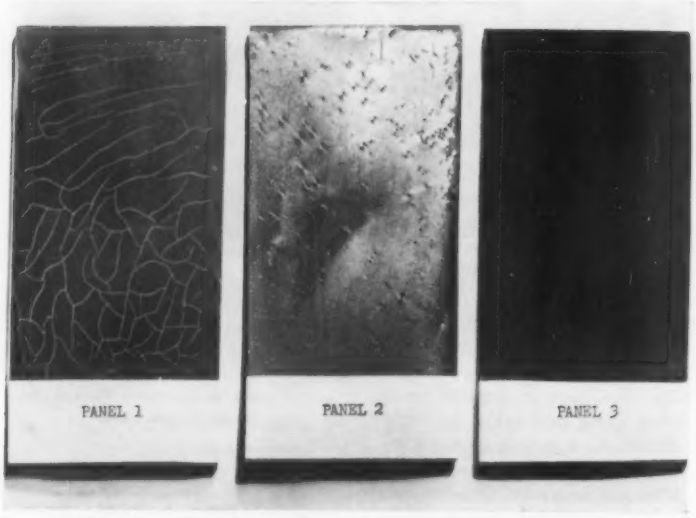

Fig. 3: Important consideration in selecting lacquers is heat resistance. In metalized panels above (brightness shows as black), three different lacquer systems were used. Panel 1 failed after 15 min. at 170° F.; panel 2 failed after 30 min. at 210° F.; panel 3, under the same conditions, did not fail

to the blank screen. This may be accomplished by several methods. However, simple water-adhering film and photographic stencils are generally used in screens for printing molded parts. Sheet stock designed for water-adhering film stencils is available from The Craftint Mfg. Co., Cleveland, Ohio, and other suppliers. It consists of a water-soluble film backed with a thin sheet of plastic or specially prepared paper.

Photographic screens are used extensively and are particularly desirable for intricate designs. Essentially the process is quite similar to printing a snapshot from a negative. The commonly used positive film is called "carbon tissue" and consists of pigmented gelatin emulsion, or a similar colloidal film supported by a backing which can be a flexible plastic.

Applying the paint: The squeegee is a tool used to force paint through the design area of a screen in the painting operation. It is made of solvent-resistant material and is equipped with a handle for hand operation or with a holding device which can be designed to be used in machine operation.

The squeegees are usually about 0.25 to 0.50 in. thick and for good printing the working corners must be kept sharp by sanding the bottom or working end. A small vertical jig with a slot about as wide as the thickness of the squeegee and with fine sandpaper in the bottom is useful for this operation. Squeegees must be kept clean and it is desirable to have a different one for each color. For a particular operation, the squeegee should be slightly shorter than the inside of the screen frame to allow ease of operation, but it should always be long enough to cover the entire design area in just a single stroke.

The flat plastic part is placed under the screen, in register, and the screen adjusted for a clearance of approximately ⅛ inch. This clearance serves the purpose of allowing a line contact as the squeegee is pulled across the screen under pressure in the printing operation. The operator takes the squeegee firmly, preferably in both hands, and dips it into the paint, leaving a small amount in front of the squeegee along its entire length. It is then pulled forward over the design with an even stroke and enough pressure to make a line contact with the plastic part as it moves. The squeegee is returned to the back, the screen lifted, and the printed part is then removed. Good screening paints or inks are available for use on practically every type of plastic including treated polyethylene. Paint must be selected, however, for the particular job and for the plastic to be decorated. Generally speaking, lacquers are more desirable than enamels for printing thermoplastics, as was the case with spray finishing. Enamels are generally more desirable than lacquers for thermosets.

Some molded plastics parts are screened by automatic or semi-automatic setups when volume production is required. This is particularly true of parts such as bottles and containers which often have curved surfaces.

Dip coating

Dip coating is economical and is used widely in decorating novelties, toys, and other objects that require only one color and are so designed that excess paint will drain off without being trapped. From the standpoint of appearance, dipping gives a very uniform paint film but it should be noted that rapid production prohibits application of uniform paint thickness. If parts are withdrawn from the dip tank at a rate faster than they drain, the film will be thicker at the bottom and excess paint will remain on the bottom edge as a line or tear. Such tears may be removed by spinning the part or by hand wiping at some extra cost. For large scale production it may be desirable to remove parts slowly for better drainage.

When pigmented paints are used, some method of agitation must be arranged to assure uniformity of the mixture. This may be accomplished by pumping material from the bottom to a point just beneath the top surface of the paint mixture or it may be done with a mechanical agitator as long as the formation of air bubbles is avoided.

The solvent system of dip finishing must be adjusted to allow good flow-out and drain without sagging. The gel time and film thickness may be controlled somewhat by use of low-boiling solvents which serve to reduce the viscosity of the paint in the

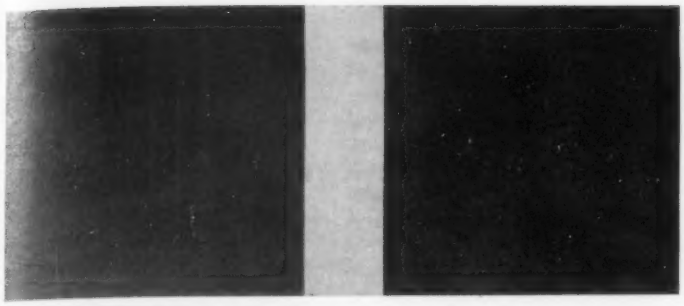

Fig. 4: Although paint was kept well mixed, panel at left, sprayed "dry," is lighter and less grainy than panel at right, sprayed very wet. Flooding is most likely to occur with paints of low viscosity. (Photos, Logo, Inc.)

dip tank but evaporate rather rapidly on application. Paint in dip tanks may lose solvent with a resultant increase in viscosity. This can be corrected by the addition of the proper make-up thinner.

Parts may be dipped singly, by hand, or by jigs that hold several parts. If they are withdrawn more rapidly than they drain, a drain board must be provided to catch drippings. Chain conveyor installations are used for large-scale production.

Roller coating

Small raised areas such as letters, figures, and designs may be decorated with paint by roller coating. This method is particularly useful in many cases as an alternate for hot-stamping. It has an advantage over spray coating for such operations in that simple loose-fitting block masks may be used or the part may be rolled without a mask. For best results the raised areas should have smooth flat surfaces and all points to be roller coated in one operation should be in one plane or at least be in a cylindrical arc. The edges and corners should be sharp for good detail.

The paint must have good adhesion since many raised areas are especially subject to wear. The solvent system must be balanced to allow flow out but the film must gel or become immobile before it has a chance to run off the raised area.

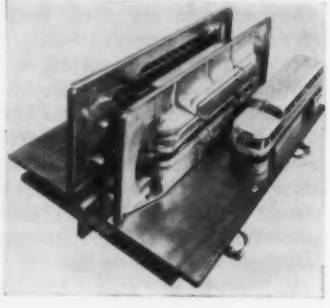
Hand rolls are commonly used for short runs and for areas that cannot be rolled by machine. A small amount of paint is placed on a flat surface such as glass and the roll is coated by rolling it back and forth in the paint. The coated roller is then moved back and forth over the raised area to transfer the paint. Automatic roller coating machines are available for handling large runs but must be adapted to the particular job.

Fill-in marking

Depressed letters, figures, and designs on either the first or second surface of plastic may be easily and rapidly filled by the spray-and-wipe method. A single depression or a series of depressions with a loose-fitting block ing the general area without a mask, or spray coating a restricted area around the depressions with a loose-fitting block mask. The job is completed by buffing or wiping the excess paint from the area surrounding the depressions. The wiping operation may be performed by hand or it can be accomplished with an automatic machine.

In the automatic setup, parts are secured in a cup-like jig and raised by an air lift for wiping. The shaft holding the parts rotates, thus wiping the part on the cloth as pressure is exerted by the opposing cushioned jig.

Enamels must be removed before they cure and it is desirable that lacquers be wiped before they are completely dry. Since regular lacquers and enamels are sticky by nature, it is always necessary to remove the last traces with a solvent which does not attack the plastic. Spray-and-wipe finishes must be formulated to avoid etching the plastic. In the case of second surface decorating, etch will show up against the color subsequently applied over the area; it will also mar appearance in the case of first surface decorating, particularly if the area surrounding the fill-in is not painted.



"Dry-wipe" formulations are generally more desirable than regular lacquers and enamels for spray-and-wipe fill-in. These highly pigmented materials are easy to use and may be wiped or buffed without a solvent over a period of time ranging from about 20 min. to several hours after spraying. Generally these materials have poor gloss as a result of the very high pigmentation and it takes them several days to reach maximum hardness. They can be packed or further decorated almost immediately after the buffing operation; if parts are to be decorated by the spray-and-wipe method, the depressions must be rather deep and narrow to avoid complete removal of the paint in the wiping or buffing operation.

Roll-leaf hot-stamping

Molded plastics parts may be decorated rapidly and economically by roll-leaf hot-stamping. The process is particularly good for relatively small letters, figures, and designs, and may be used for reasonably large areas if care is taken that the parts are properly designed.

Roll-leaf consists of a flexible ribbon of paper, cellophane, cellulose acetate, or similar sheet stock with a colored coating on one side. The hot-stamping proc-

Fig. 5: Book-type lip mask for painting wide dark stripe around center and narrow dark stripe around top of toy. (Photo, Conforming Matrix)

ess consists of transferring this coating from the flexible backing to the molded plastic part by pressure and heat.

Roll-leaf is supplied in a wide range of both transparent and opaque colors, and is available with several different types of coatings formulated for adhesion to various kinds of plastics. Hot-stamping equipment varies from the manually operated press to the completely automatic setup.

The plastics part is nested firmly in or on a jig under the head of the press, and the roll-leaf, fed under the head of the press, is brought into pressure contact with the plastic by an electrically heated die in the press head. Contact is held for a dwell time sufficient to soften the coating and transfer it to the plastic surface where it is bonded by the heat and pressure. Contact is then broken and the stamped part removed for further processing or packing. No drying of the part is needed.

Hot-stamping introduces rather severe stresses into plastics parts and it may be desirable to anneal such parts before decorating them further with paint or before putting them into use.

Clean-up and inspection

Clean-up and inspection are important last steps in the decorating process. The amount and type of cleaning required depends on the type of part decorated and the type of decoration used. For example, clear parts that have been spray-decorated on the second surface may have a collection of paint over-spray on the first surface that can be removed by wiping the entire area with a solvent that does not attack the plastic. For most plastic surfaces this is a simple operation when lacquers are used. However, when enamels are used, over-spray must be removed before it sets or cures. Such a wiping operation will remove other surface contaminants including dust. Antistatic preparations may serve as a cleaning solvent and at the same time reduce the static charge on the plastic part, thus protecting it from dust collection in shipment and future use.

The amount and type of inspection depends on the particular job and a statistical study of the operation. A sufficient number of parts should be inspected to assure shipment of parts that will meet the customer's specifications. Inspection of decoration should include a visual check for craze lines, etched surfaces, color of decoration, gloss of finish, coverage, and general appearance of the over-all job.

METALIZING

BY PAUL W. PATTON*

Metalizing or vacuum metalizing is the process employed to deposit metal film on plastic, wood, metal, and other base materials by vacuum thermal evaporation. The term metalizing also applies to such other processes for depositing metal film as metal spraying, chemical reduction, and electroplating.

Characteristics and uses

Vacuum metalizing offers many advantages as a finishing technique for plastics.

1) The process involves little or no heating of the base material, permitting metalizing of heat-sensitive thermoplastics materials.

2) It is an economical method for increasing a product's merchandising appeal to the consumer.

3) Metalized films surpass in brilliance all but the most carefully buffed, polished, and electroplated metals. Reflectivity of aluminum-metalized films usually exceeds 90 percent.

4) Since metallic film is opaque and hence independent of the color of the base material, mixed-color remnants of raw material can be used.

5) Metalizing is adaptable to practically all plastic materials.

6) Molded and fabricated objects can be handled in batch machines. Flexible sheet in roll form is processed in semicontinuous units.

7) Most metals can be deposited by metalizing, although aluminum is used in practically all industrial applications because of its brilliance, low cost, and ease of evaporation. Gold and silver are also used, but in more limited amounts. Platinum, tungsten, nickel, chromium, tantalum, and molybdenum can also be applied.

8) The process is versatile, making it well suited for both job shop operation and long runs.

Decorative and functional

For decorative use, metalizing is to the plastics industry what plating is to the metal-working industry. Plastic novelties, toys, and jewelry items were the first products to take advantage of the low-cost decorative metallic film. Reflectors, advertising displays, and special packaging effects are further examples. Decorative medallions are universally used in automobiles and appliances, and a number of plastic hardware items for general use in plumbing, electrical, and builders' hardware categories are growing in popularity.

Functionally, metalizing offers numerous advantages in places where optical and electrical properties are required. Metalized reflectors for camera flash attachments, bicycle lights, flashlights, automotive lamps, and home lighting devices have opened new markets for plastic products. Metalized printed circuits on plastic base materials, electrical capacitors, and metalized electro-

* Mgr., Vacuum Process Equipment, National Research Corp., 70 Memorial Dr., Cambridge 42, Mass.

Recent Developments and References were prepared by the editors.

static shields on plastics housings for electronic devices are examples of the use of metalizing to produce electrically conductive paths.

Though limited to the production of thin films (the coating seldom goes over five millionths of an inch in thickness), vacuum metalizing is often used on a nonmetallic base to provide an initial electrically conductive coating that can subsequently be built up by electroplating. Phonograph record masters are among the products made by this process.

Designing the part

In designing a part which is to be metalized, blind holes having a depth of more than 1½ to 2 times their diameters should be avoided if the coating is expected to cover the inside of the holes. Sharp edges on wearing surfaces should also be avoided since these areas are subject to concentrated wear which may remove the coating.

The size of the object is, of course, limited by the dimensions of the production coaters—generally, 5- to 6-ft.-dia. cylindrical tanks containing work-holders normally permitting 16-in.-dia. clearance. Generally speaking, the most economical utilization of the coater capacity is made by processing several small parts, rather than a few large parts.

Complicated shapes can be handled with good success, thanks to the excellent "throwing power" of the metalizing process and the opportunity for rotating or revolving parts during the coating process, by means of planetary-motion jigs.

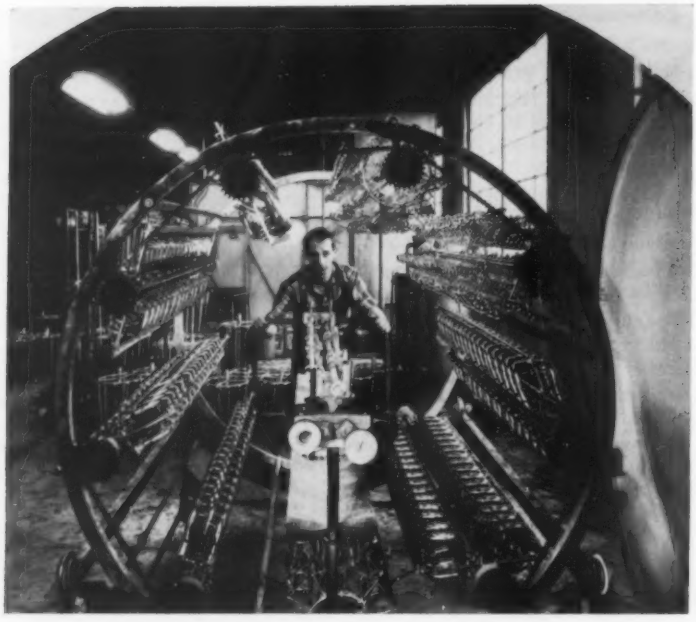
Preparing the surface

Like any quality fiinishing process, materials to be metalized must be clean and free of imperfections when flawless results are required. Lubricants and release agents used in the production of injection molded parts can cause trouble in lack of adhesion and off-color coatings and should be avoided.

Plastics parts having rough or otherwise imperfect surfaces can be made suitable for metalizing by the application of a base coating consisting of an organic finish that will not plasticize the base material. With durable thermosetting plastics which are subject to hard usage, a bake-on finish is appropriate. Less costly thermoplastic materials, which are not subject to rigorous use conditions and which cannot tolerate high-temperature baking can be coated with air-dry or force-dry lacquers. The lacquering operation serves another useful purpose by sealing the surface of the plastic so that it does not give off undesirable volatiles from contained solvents which evaporate when the vacuum is produced.

Depositing the metal

The actual application of the metallic film is one of the quickest, most economical steps in the process. The parts to be coated are loaded in holders. A number of loaded holders are clamped to a jig prior to loading in the coating tank. When all is ready, the tank is opened, the loaded jig is inserted by means of a dolly or conveyor, the door is closed, and the tank exhausted to a pressure of approximately one millionth of an atmosphere (0.5 microns of Hg). Depending on the capacity of the machine and the properties of the load, some 10 to 30 min. may be required to exhaust the tank to the necessary operating pressure.



When aluminum is the metal to be deposited, small aluminum staples are hung from coils of stranded tungsten wire filaments. These filaments are connected to the source of the current through several electrodes running lengthwise through the axis of the vacuum chamber. All other metals are evaporated from troughs fabricated of tungsten or molybdenum sheet into a V-shape designed to hold the molten metal.

Metals are heated by direct resistance. A variable power supply brings this "source" up to a sufficiently high temperature to cause the metal to vaporize. The vapor, invisible to the operator as he watches through a sightglass in the side of the chamber, condenses on all exposed surfaces on the inside of the chamber. The heating and evaporation of the metal from the source usually requires less than a minute. Upon completion of this step, the pumping system is valved off, air is let in, the door of the chamber is opened, and the coated work is removed. Individual objects may be left clamped to holders until they are transferred from the jig

RECENT DEVELOPMENTS

In order to produce a faster metalizer the vacuum pumping system of the *Model 427* 72-in. vacuum metalizer has been redesigned. It now has two 16-in. "Ring-Jet" diffusion pumps plus a 6-in. booster pump; these pumps have reduced the time needed to pump down to 0.5 micron to 6 min. or less. The new pumping system is also better able to handle unusual operating conditions, e.g., heavy outgassing from the work or from contaminated chamber walls. The automation features of the older model have been included in the new model. *F. J. Stokes Corp., 5500 Tabor Rd., Philadelphia 20, Pa.*

A new vinyl-based strippable coating (*Vacuumguard*) can be sprayed or brushed on the inside surfaces of vacuum metalizing equipment to keep the chambers clean. A 2- to 3-mil coating is usually sufficient. When it is properly applied, the coating will be ready for use in less than a day. It is said to be the only such coating that will not outgas under the high vacuums involved in metalizing. When the excess evaporated metal is to be removed, the strong (tensile strength over 2000 p.s.i., elongation about 185%) film is simply stripped out of the metalizer. Precious metals may be recovered from the stripped film simply by dissolving it in aromatic or ketone solvents. *Guard Coatings Corp., 8-05 43rd Ave., Long Island City 1, N. Y.*

Large vacuum metalizing unit provides generous unobstructed interior spaces. A wide variety of sizes and shapes can be handled with work holders and jigs

to a conveyor or materials-handling truck which may be employed in the top-coating process.

Decorative effects

The process thus far described places the metalized finish on the outside surface of the object. This arrangement is known as "first-surface coating" and is most widely used. The exposed surface, being only a few millionths of an inch thick, and consisting of a soft metal, requires protection if it is to withstand abrasion, weather, or other conditions of normal use. Such protection is accomplished by applying a second organic transparent finish over the metalized surface. Color, e.g., gold, copper, bronze, etc., can be obtained by dip-dyeing the lacquer top-coating with an appropriate tint.

An alternative to the first-surface coating decorating technique is the second-surface coating method in which the metalized film is applied to the back of a transparent plastic part permitting the coating to be viewed through the base material. In such an arrangement, the plastic serves to protect the finish. It is used in more expensive decorative medallions, e.g., automotive horn buttons, medallions for appliances, etc. Color in second-surface work is obtained by applying tinted lacquers to the metalized surface.

Equipment and plant

The metalizing unit is the most important and, frequently, the most expensive single piece of equipment in the process installation. On the smaller jobs, the coating chamber is a glass bell; in the more common production installations, a steel tank is used. In either case, the chamber is equipped with a vacuum pumping system that includes mechanical and diffusion vacuum pumps and necessary valves. In the batch coater, in particular, large pumping systems are important to minimize the length of time required until the source can be energized after loading, and the coating deposited. In the usual batch operation, one coater is supplied with two jigs so that one can be loaded and unloaded while the second is in the chamber. Controls for valves, filament power supply pumps, and air bleed are generally centralized in a panel to simplify operation and to permit the provision of sequence control which helps to avoid errors in operation.

Equipment now available will operate with a minimum of downtime provided preventive maintenance schedules are practiced. One cause of downtime is the accumulation of metal on the inside of the tank. This may be removed, in the case of aluminum, by scrubbing with a solution of sodium hydroxide. This practice involves the use of water, residues of which can cause lengthy pump-down cycles until thoroughly outgassed. More recently, a strippable organic film that can be applied to the inside of the clean tank has been introduced. When it is desired to remove the accumulation of evaporated metal, the flexible coating is peeled from the inside of the tank and a new coating applied.

In setting up the metalizing operation, provision should also be made for applying base and topcoats, as well as for baking or airblast-drying facilities. Lacquers may be applied by hand spray, automatic spray, electrostatic spray, dipping, or flow coating processes.

As in any organic finishing operation, the complexity and cost of the installation must be matched against the character of the parts to be coated and the production levels required. In the metalizing operation complete exclusion of channels, tears, and orange peel effects is particularly important, because the application of a highly reflective metallic film to imperfections serves to magnify them. Flow coating is popular because of the high-quality finishes it provides and the economics offered by the minimized finish losses. Similar requirements pertain to the top-coating operation. Conventional baking or dry-air-circulating ovens are required depending upon the nature of the base material and the types of finishes employed. Base coats in particular must be thoroughly baked or dried out to minimize evaporation and out-gassing of solvents when the coated part is introduced into the metalizing chamber for processing.

Continuous roll metalizing

In the continuous metalizing process, a roll of plastic, e.g., polyester film, acetate, styrene,

etc., is traversed across a source of continuously vaporizing aluminum. Webs up to 60 in. wide, traveling at several hundred linear ft./min., thus receive a brilliant metallic finish. After metalizing, the film or sheet is then rewound on a take-up roll.

Shapes die-cut from metalized plastics film or sheet may be used as labels or sequins in decorative applications. Considerable activity has also taken place in vacuum formed metalized materials for the sign and display field. Fashion applications include coverings for wallets and shoes, and a decorative textile yarn made from metalized polyester film slit into narrow widths. Metalized polyester film can also be laminated to heavier vinyl sheeting and embossed to produce a product which will be decorative.

Cathodic sputtering

Cathodic sputtering is very similar in operation to vacuum evaporating, except that the pressure required is not as low. Also, the metal is applied by producing a high-voltage differential between the source and the object to be coated, rather than by heating. The metal to be deposited serves as the cathode. Under the influence of a high voltage, metal atoms leave the cathode and are deposited on nearby surfaces.

The resultant coat is similar in appearance to that obtained by vacuum evaporation, but the rate of application is much slower (rates of deposition by sputtering limit the film speed to about 20 ft./min.).

Applications are generally confined to precious metals or where closely controlled, extremely thin films are desired. Aluminum can not be sputtered.

Electroplating†

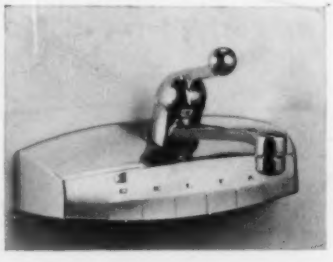
Very often, it is desirable to build up a heavier deposit of metal on plastics surfaces than can be obtained with conventional processes. In such instances, electroplating is used.

Successfully to electroplate a layer of copper on a vacuum metalized film of copper, certain precautions must be taken. The usual procedure for normal electroplating of metal parts calls for a few seconds of "back flash" before the plating actually begins. This "back flash" is a cleaning operation which removes a slight layer of metal oxide from the surface of the object to be plated. It is done by reversing the current for a few seconds, thereby making the object to be plated the anode instead of the cathode. In plating, the D.C. current flows from the anode to the cathode and the metal builds up on the cathode. During the "back flash" cleaning operation, the cathode (which is the anode during "back flash") will be stripped of a thin layer of metal. Thus, this operation cannot be performed on a vacuum metalized film.

For electroplating on a thin, evaporated film, a common copper sulfate plating bath, slightly on the acid side, should be used. The temperature of the bath should be between 90 and 100° F. A voltage of 7½ v. and a current of 50 amps/sq. ft. (0.35 amps/sq. in.) should be used. This rating will deposit about 0.0025 in. per hour. If higher current is used, burned-out areas will be created in the vacuum metalized film.

Chemical reduction

There are many different techniques, solutions, and sensitizing agents for use in the chemical reduction method. In this type of metalizing, a chemical compound is reduced to metal. This is not a simple operation, and must be carefully controlled.



The chemical reduction method is attractive to companies which require a special "softer" finish, and a more perfect duplication of gold or silver than is obtained by dyeing evaporated, coated aluminum.

The seven basic steps required in the reduction techniques are: 1) degreasing; 2) rinsing in fresh water and drying; 3) sizing with a thin coat of lacquer and baking dry; 4) sensitizing, then flushing with fresh water and drying; 5) silvering, by reduction, then flushing again with fresh water and drying; 6) coating with lacquer and baking dry; and 7) dyeing to the required color and drying.

The most important precaution to be observed in each of these steps is that the pieces should not be allowed to come in contact with any foreign objects which might deposit a thin film of grease or oil on them. Special holding fixtures must be designed and clean, lint-free gloves worn.

Mold lubricants are deadly to all metalizing processes and must be completely removed.

Clear plastic trim for sink faucet is metalized on second surface to match appearance of polished chrome plate

Metal inlaying

There are several patented processes for inlaying metal in transparent or opaque plastics.

Most common is the four-step process used for a *surface inlay*. A recess of appropriate shape is formed in the plastics object, either during the molding operation or by subsequent engraving. A thin strip of hard metal, about half as thick as the depth of the recess, is placed in the bottom of the recess. A slightly curved metal inlay is placed on the hard base metal strip, concave side down. Pressure is applied to the convex top of the inlay, and, because the hard base metal has more resistance to the pressure than either the inlay or the plastics, the inlay is forced to spread out on the sides, penetrating the walls of the recess and permanently locking itself in place.

The *reverse inlay* is a patented process used with transparent plastics. A cavity molded in the back of the piece receives a two-layer metal inlay. If the first piece is stenciled, an effective design can be obtained by using a contrasting second piece. An etched or lithographed design is also possible. The design may be

† Paragraphs on Electroplating, Chemical Reduction, and Metal Inlaying prepared by J. Gordon Seiter, Mgr., High Vacuum Div., F. J. Stokes Machine Co.

inlaid in duplicate so that it can be seen from both sides. If the sides of the cavity are specially formed, the effect is that of a series of planes.

Another inlay process is the *foldover*, in which the plastic part is molded with an excess of material around the edge of the cavity. After the inlay has been inserted, it is anchored in place by softening the excess material and forcing it over the edges of the inlay. The *sandwich* process uses two pieces of plastic, one opaque and one transparent. The inlay is placed in a recess in the opaque piece and the transparent piece is then bonded to the opaque surface.

WELDING PLASTICS

BY J. A. NEUMANN* and F. J. BOCKHOFF†

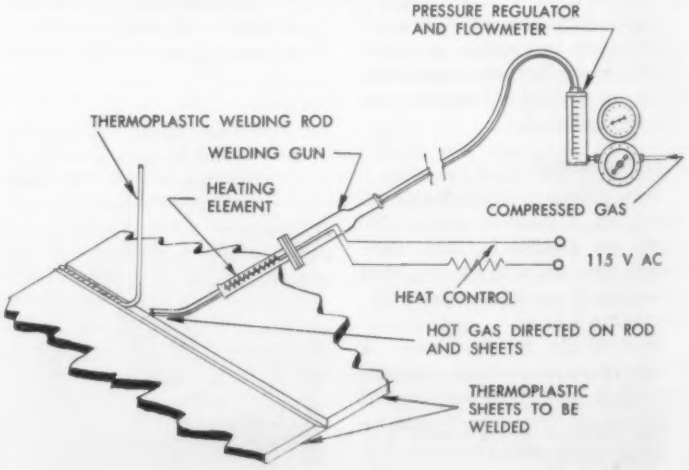
Recent Development

Greater versatility and easier handling are the attributes claimed by the manufacturer for the new Model P hot-gas plastic welder. Heating elements are extra sturdy; standard heater delivers 320 w., but heaters of 180, 240, and 600 w. are available on request. Elements can be changed in a few minutes and the range of wattages permits the safe welding of all thermoplastics from thin polyethylene to thick PVC. A molded plastics handle gives both better grip and better insulation than handles of earlier models. *Seelye Craftsmen, 984 Central Ave., Minneapolis, Minn.*

The adaptability of the hot-gas welding technique (1, 2, 3)[1] allows the fabrication of almost any type or size of process equipment. Large forms can be joined and extended to form duct work, exhaust systems, reactor tanks, and pipe lines, as well as tank liners.

In order to be weldable, a thermoplastic must possess a reasonable melting range rather than a sharp melting point. A melting range is important in allowing control of the welding process.

Most of the thermoplastics can be welded. Polyethylene and polyvinyl chloride are particularly adaptable to welding and these materials are used to the greatest extent.



The newer linear or high-density polyethylenes can be hot-gas welded to produce joints of satisfactory strength. In addition, saran, polyacrylic esters, and fluorothene are among the plastics materials that have been successfully welded.

Technique

Basic thermoplastic forms such as sheet, rod, extruded tubing, centrifugally-cast tubing, and welding spline are commercially available in a large variety of sizes and materials. These forms are subsequently joined by welding to produce most finished fabrication.

A schematic diagram of the general welding technique is illustrated in Fig. 1, below. Heated gas from the welding gun is used to join the components to be welded, using a rod of the same composition. Compressed air is used for many plastics, particularly the rigid vinyls. When welding polyethylene, however, an inert gas such as nitrogen is usually used to prevent any possible surface oxidation which

Fig. 1: Diagram showing the components and a typical arrangement used in the plastics welding process. Heated gas from the welding gun is used to join components together. (Sketch, American Agile Corp.)

[1] Numbers in parentheses link to References on page 842.
Recent Development was prepared by the editors.

may produce faulty bonding. As the surface of the rod and sheet are softened, the filler rod is continually forced into the weld bed under slight pressure. Unlike metal welding, complete fusion does not take place. Although it is important that the exterior of the welding rod be soft in the case of polyvinyl chloride or transparent in the case of polyethylene, it is also important to maintain rigidity of the rod core in order to maintain proper weld control.

Both electrically-heated and gas-heated welding guns are available. The schematic diagrams of both types are shown in Fig. 2, right. Several gun tips are available in straight and curved form, depending upon the operator's preference. Usual orifice temperature in welding varies from 400 to 600° F. and is controlled by regulating the current to the heating unit in the electric gun or by varying gas pressure and flow rate. Normal gas pressure varies from 5 to 15 p.s.i.g. and optimum flow rate for most welding is approximately 2 cu. ft./minute. The distance between the tip of the gun and the weld bed usually varies between 1 and 2 in. and within this distance a temperature drop of about 200° F. is experienced. Linear welding speeds of from 5 to 8 in./min. are commonly realized. The welding speed is dependent upon both the type of weld and the skill of the worker operating the gun.

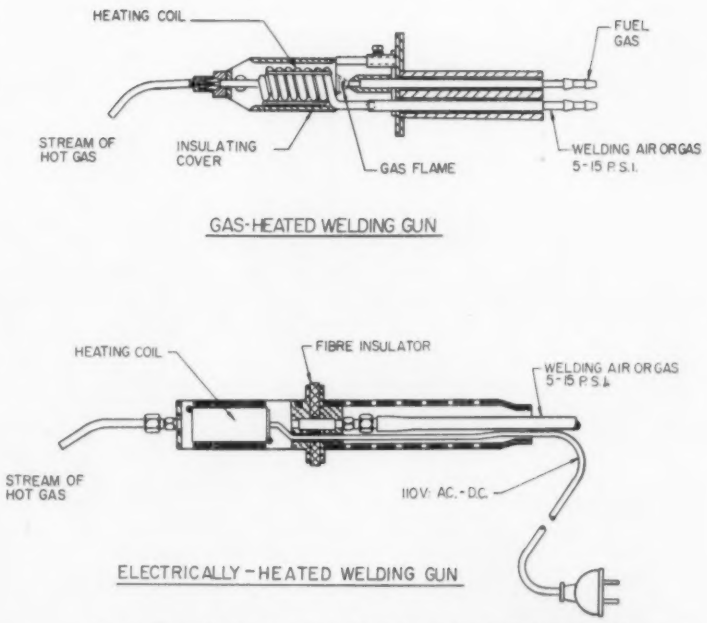

Fig. 2: Schematic drawings of gas-heated and electrically-heated welding guns. Orifice temperatures are controlled by varying gas pressure and flow rate (in gas-heated gun) or by regulating current (in electrically-heated gun)

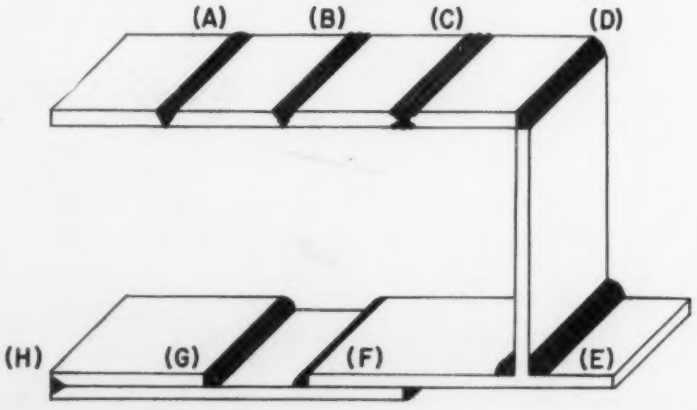
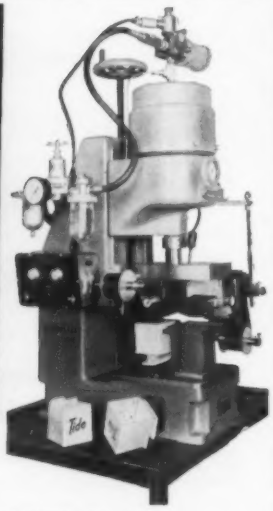
Bonded strength

As is true for all bonding and welding, bond strength is improved by a proper preparation of surfaces to be joined. When making a butt-weld, the edges to be joined should be beveled to include an angle of 60°. When lap-welding and fillet-welding, the surfaces to be joined should be solvent-cleaned or mechanically roughened. Generally, solvent-cleaning alone is satisfactory for the preparation of fillet-welds.

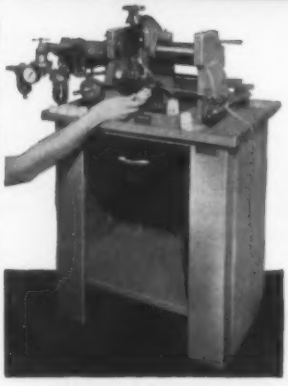


It is important that any of the lubricants or mold release agents used in the fabrication of basic components be removed completely from the surface before beginning to weld. Several weld types are illustrated in Fig. 3, below.

The correct angle between filler rod and weld bed varies with the type of material being welded. Fig. 4, p. 840, illustrates the welding of polyethylene in which the rod is turned to an obtuse angle in order to exert sufficient bonding pressure on the fused surfaces. In the case of more rigid materials such as linear polyethylene and nonplasticized polyvinyl chloride the rod is held at approximately 90° to the weld as shown in Fig. 5, p. 841. A perpendicular filler-rod angle is used with all rigid thermoplastics.



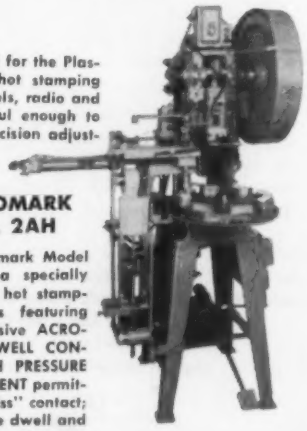
Testing methods



The strength of a weld is given in terms of a weld value which compares the breaking stress of

Fig. 3: Six basic weld types: A) single-bead, single-V butt weld; B) multiple-bead single-V butt weld; C) multiple-bead double-V butt weld; D) corner weld; E) double fillet weld; F) lap weld; G) lap-bead; and H) edge weld. Each type requires special surface preparation, e.g., beveling, solvent cleaning, etc.

THE LAST WORD IN HOT STAMPING MACHINES



ACROMARK No. 250

The latest improved, flat bed type of Hot Stamping Press. This Acroleaf Press has up to a 6" x 6" die area, and 6" roll-leaf width, mouth 9½" and throat 8" deep, all within 370 lbs. not including dies and controls.

Fully adjustable, sturdy construction, air operated, automatic temperature control and Acroleaf feed. FOR GENERAL PURPOSE WORK. May be easily tooled for SPECIAL jobs. For example—above application requiring INSIDE and OUTSIDE imprinting, was done at one stroke. Several standard sizes are available.

ACROMARK No. 9AH

THE general purpose marking machine designed for the Plastics Industry and THE ACCEPTED STANDARD hot stamping machine for peripheral marking of counter-wheels, radio and TV controls and all cylindrical work is powerful enough to mark steel and cast iron continuously while precision adjustments permit "kiss" imprints on the most delicate thermoplastics. Both bevel edge and straight controls are accurately and quickly hot stamped completely around the circumference at one loading. The work is accurately held and independently gear driven in proper registry with the engraved marking die. Automatic Acroleaf feed, temperature control, and speed control is standard on 3 stock models with automatic cycling, two-color set-ups, etc. available on special order.

ACROMARK No. 2AH

The Acromark Model 2AH is a specially designed hot stamping press featuring the exclusive ACROMARK DWELL CONTROL and PRESSURE ADJUSTMENT permitting a "kiss" contact; adjustable dwell and then full pressure.

This machine should not be confused with a standard power press to which hot stamping attachments have been added.

MADE only in Elizabeth, N.J.

For "the last word in hot stamping machines", write for catalog of series specified and send drawings or samples of products to be marked indicating daily production needed. Indicate Series 250, 9AH or 2AH. Representatives in most industrial areas.

ACROMARK

THE ACROMARK COMPANY

5-15 MORRELL ST., ELIZABETH, NEW JERSEY

"The Original Marking Specialists"

Fig. 4: Rod is turned to an obtuse angle in laying a polyethylene butt weld. (Photo, American Agile Corp.)

a welded specimen to the ultimate tensile strength of the parent material:

$$W = \frac{S_w}{S_p} \times 100$$

where: W = weld value (%); S_w = break stress on the weld (p.s.i.); and S_p = ultimate tensile strength of the parent material (p.s.i.)

Branched polyethylene welds show strengths varying from 95 to 100 percent. Linear polyethylene exhibits lower weld values, in the neighborhood of 50 to 60 percent. It must be remembered, however, that the actual break stress of the weld is still higher than that of a branched polyethylene weld, due to the much higher ultimate tensile strength of the parent linear polyethylene. Here, the actual weld value is deceptive unless one is also familiar with the ultimate tensile strength of the parent material. Polyvinyl chloride welds exhibit weld values in the range of 75 to 90 percent.

The weld value of a crystalline material such as polyethylene varies considerably with the molecular structure of the basic polymer. Weld value usually increases with increasing molecular weight and also increases with increased molecular chain branching or decreasing crystallinity. It must also be pointed out that the weld strength of a crystalline polymer such as polyethylene is a function of time and usually increases exponentially from the time at which the weld is completed.

This gradual increase in the

weld strength with time is due to the reorientation of the molecular structure as it approaches crystalline equilibrium. With branched polyethylene welds, maximum strength is reached within 4 hours. The quality of a weld has also been shown to be dependent to a large extent upon the skill of the operator (4).

Ineffective welds can be produced if air is occluded while laying the filler beads. Air occlusions can usually be observed in natural polyethylene by the use of a strong inspection light held at an oblique angle in relation to the weld.

Minute cracks and pores in welded seams are often detected by spark testing. This is particularly useful for the examination of tank-liner welds, since a steel supporting tank serves as a good electrical ground.

Radiography has also been used successfully for locating defects in plastics welds (5). This is particularly useful and efficient in checking welds within closed assemblies such as welded globe valves.

Applications

Practically any equipment that can be fabricated from steel can be made from plastics. The basic nature of the welding technique allows the fabrication of large-size structures. A pulse extraction column, for example, measuring 10 ft. high and 20 in. in diameter, has been completely fabricated of polyethylene, using the hot-gas welding technique. The wall thickness of the poly-

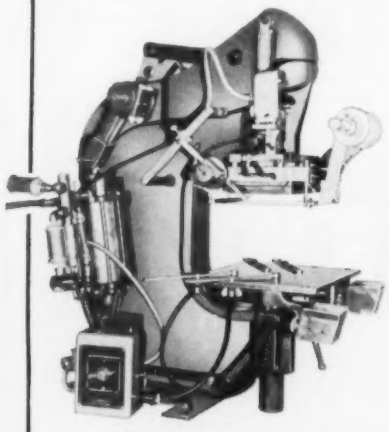
Solve your Plastic Marking problems

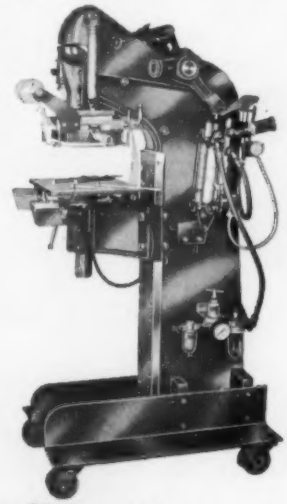


with KENSOL Hot Stamping Presses

Kensol 35T

AIR-OPERATED POWER PRESS
for items up to 2 ¼ inches high

A ruggedly constructed, air-operated, electrically dwell-timed power press with 4 x 8 inch imprinting area and a 3 inch head stroke. Also available as a hand operated press which can be later converted to power in your own plant. Weighs 280 pounds.



NEW Kensol 60
HEAVY-DUTY POWER PRESS
for items up to 5½ inches high

A completely new Kensol model available with one or two main cylinders. When equipped with two cylinders, extremely high pressures are developed to stamp work well out of the range of air-operated equipment previously available. Press has 3 inch head stroke, and is available with 6 x 8, 9 x 12 and special impression areas up to 24 inches wide. Weighs 490 pounds.

NEW Kensol 110
HEAVY-DUTY POWER PRESS
for items up to 24 inches high

A completely new Kensol model available with one or two main cylinders. Bed can be lowered to accommodate large plastic pieces (refrigerator parts, radio cabinets, etc.) up to 24 inches high. When equipped with casters, the g110 can be rolled up to molding machines, etc. Weighs 650 pounds.

Send for complete information. Literature on all Kensol equipment will be sent on request. Included will be information on large size roll leaf attachments, Kensol g20 turntable attachment, power sliding table, automatic feeding devices and other pertinent information.

Forrest carbide tipped blades give up to 50% longer cutting life between sharpenings than regular carbide blades, and have up to 20 times longer cutting life than ordinary steel blades.

☐ **Smooth cutting?**

Forrest blades are precision tools, custom ground with a micro-finish to assure chip-free and splinter-free cutting on such plastic materials as acrylic, styrene, polyethylene, urea, laminates, printed circuits.

Write for illustrated brochure and for price lists.

Forrest

MANUFACTURING COMPANY, INC.

P.O. Box 189—231 Highway 17, Rutherford, N. J.

"YOU CAN TELL A FORREST BLADE BY ITS CUT"

ethylene sheet used for the application was 5/16 inch. Separation plates were fabricated of 1/2 in-thick polyethylene sheet.

Hot-gas welding also provides a positive and economical means for the fabrication of small items of a short-run nature, such as polyethylene laboratory tanks.

Actual applications are discussed extensively in available literature (6, 7).

Conclusion

Hot-gas welding is a sure and quick method of joining plastics with optimum strength. Great strides are presently being made in the development of automatic welding machines to produce consistently good welds in 25% of the time ordinarily required for manual welding.

More and more plant engineers are discovering the applicability of welded plastics and are installing replacements and fabrications with these materials. In addition, plastics-welding maintenance departments are being initiated to a greater extent to accommodate the demand of process industry for the trouble-free performance provided by corrosion-resistant plastics equipment.

FIORE SPRAY MASKS
are the answer

©Walt Disney Productions

No paint job is too complicated for a Fiore spray mask.

No matter how intricate the painted detail on your product, Fiore can design a spray mask that will give you exact registration—even on irregular and contoured surfaces.

Every Fiore mask is made by the electroforming process, to insure accurate reproduction of even the finest detail, including a great variety of products—such as name plates, toys, novelties and displays. Fiore has also developed a special technique for those hard-to-handle spots, including doll's eyelashes.

MASK FIXTURES

Fiore also makes jigs and fixtures to enable sprayers to place masks in exactly the right position, with a minimum of time and effort.

In this illustrated booklet you'll find a thorough account of the Fiore method. Write for your FREE copy, and find out how you can improve your spraying operations.

AUTOMATIC EDGING of SPHERICAL MOLDINGS

NASH 103 AUTOMATIC FLASH LATHE

(Continuous Turret Operation)

A Ten Spindle Machine . . . produces up to 90 pieces per minute

Automatic removal of parting line flash using spring loaded file flashing units or special tooling. Accommodates diameters up to 4½" . . . height adjustment up to 8". Uniform results, confines flash removal to minimum line.

NASH 103-B AUTOMATIC FLASH LATHE

(Intermittent Motion on Turret)

For Finishing Operations On Moldings That Require Controlled Index and Stop, At Working Stations

Tooling can be provided for cutting, belt abrasive action, buffing, etc. Full control on rate of index, gradual approach to tooling and metered time at stop position.

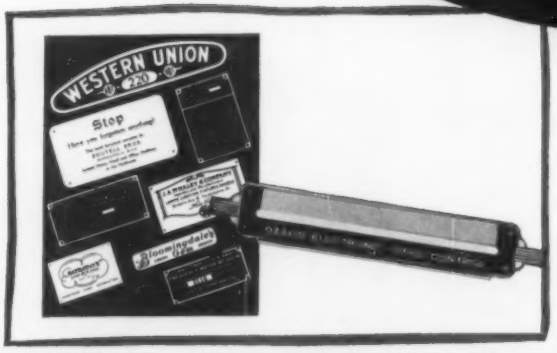
Table arrangement to mount a variety of tooling performing successive operations on the moldings.

NASH 116 ROTARY EDGER

. . . for the edging of plastic dinnerware

Four motor-driven belt units remove parting line flash and buff-edge without destroying contour. Will accommodate plates up to 11½", variable rate of production from 10 to 30 pieces per minute.

Produces proper finishing results superior to hand methods at fraction of finishing cost. The standard machine for the edging of plastic dinnerware.



We will be pleased to work with you on your finishing problems and make the correct machine recommendation on the basis of samples or prints you furnish.

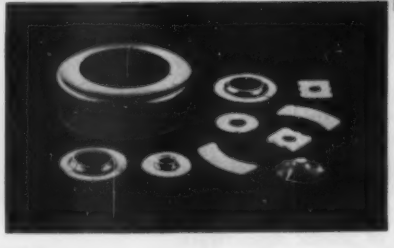
HOW Sillcocks-Miller CAN HELP YOU WITH PRECISION-FABRICATED PLASTICS

NAMEPLATES . . . Distinctive identification fabricated of the right plastic to resist temperature and weather and protect your message.

DIALS . . . Fabricated to close tolerances and formed to any shape to meet your individual needs.



SCHEMATIC DIAGRAMS . . . Reproduced on plastics and laminated for sharp definition, clean appearance and durability.

Since 1910, Sillcocks-Miller has specialized in the precision-fabrication of plastics. This long experience is available to give your products the practical advantages of the plastic material best-suited to your requirements. The latest techniques are combined with complete facilities for cutting, printing, stamping, cementing, milling, turning, blanking, drawing, forming, laminating and assembly. Send your specifications for recommendations and quotations.

SAVE ON MOLD COSTS for Small Parts!

A special fabricating process developed by Sillcocks-Miller engineers saves on cost of molds for small parts, such as insulators and washers. You get this saving without sacrifice of quality or service life. Write for details and recommendation.

PIONEERS IN THE PRECISION FABRICATION OF PLASTICS SINCE 1910

REZ-N-KLEEN
for cleaning acrylics
POLY-KLEEN
for cleaning polystyrene
REZ-N-POLISH
for polishing acrylics
Cleaners & polishers
Manufacturers of plastic products the world over have used Schwartz cleaners and polishers for a multiplicity of jobs. For polystyrene plastics or acrylics, Schwartz cleaners are "a must" in your scheme of things.
REZ-N-KLEEN:—A liquid cleaner for removing masking tape and other foreign matter from lucite or plexiglass.
POLY-KLEEN:—A liquid cleaner for removing lacquer over-spray, grease, adhesives, etc. from polystyrene. Will not craze or mar even the thinnest sheet.
REZ-N-POLISH:—A powdered cleaner, polisher, and anti-static agent for removing haze and cloudiness on acrylics.
Free samples and literature are yours on request.

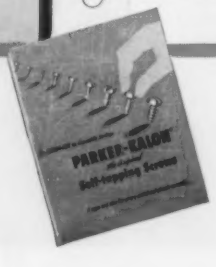
plan fastenings to trim ASSEMBLY'S "BITE" IN PRODUCTION COSTS

Assembly's percentage of total production cost runs from 10% or less in simple "gadgets" to as much as 75% in modern aircraft. There is no room for needless assembly expense in any product.

In 7 out of 10 products surveyed for applications, the P-K Fastening Method has proved simplest and speediest. You eliminate the extra cost of tapping for machine screws, and the expensive and troublesome inserts that slow up molding. Assembly *starts* several steps closer to the finished job. And, fastenings are stronger, more resistant to vibration.



PLAN BETTER PLASTICS ASSEMBLIES WITH THESE P-K AIDS

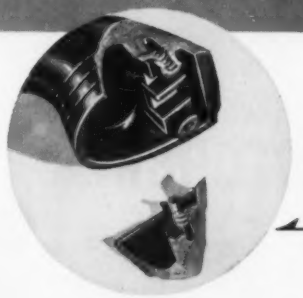
ASSEMBLY ENGINEERING SERVICE P-K Assembly Engineers are fastening experts who are ready to work with you and point out how to save operations, simplify assemblies, and add product strength. Since P-K offers a complete line of Self-tapping Screws, recommendations are unbiased. The P-K method fits the right screw to the job. A P-K Assembly Engineer will call at your request.

TECHNICAL LITERATURE Parker-Kalon has prepared useful information in several forms to assist you in planning assemblies. Some are shown below. Write for the ones you need.

	Type Z* HEX HEAD Z*	Type F-Z
types	TYPE Z ALSO MADE WITH PHILLIPS HEAD	ALSO MADE WITH PHILLIPS HEAD
uses	Primarily used for fastenings in cellulose acetate and nitrate compounds, polystyrenes, and laminated phenolics. Forms thread as it is driven. Can be removed and replaced.	Primarily used for fastenings to comparatively thin sections and bosses in friable and brittle plastics. Combines coarse pitch thread advantages of Type Z with thread cutting features of Type F. Five cutting flutes. Can be removed and replaced.
metals	Standard screws are hardened steel. Available with any plated or other finishes in common use. Stainless Steel (18-8) Type Z (not Hex Head) are also standard in some sizes. Furnished on special order in Type 410 corrosion resistant Steel, hardened.	Hardened steel, available with any plated or other finishes in common use. Also Type 410 corrosion resistant Steel, hardened. Type F-Z is not stocked, but is available on special order.
head styles	Standard head styles are Round, Binding, Stove, Flat, and Oval, as well as Hex Head shown above.	Available with Round, Binding, Flat, Oval, or Hex Head.
special forms	 (illust.) Non-standard forms of Type Z can be developed and furnished on special order. Typical modifications are illustrated.	 (illust.) Special forms of Type F-Z can be developed and furnished to order. Typical modifications are illustrated.

P-K Self-tapping Screw Bulletin
48 pages, describes all types, tells where and how to use what screw, shows many plastics applications. Ask for Form 430.

P-K Engineering Standards
64 pages, gives standard head and thread dimensions of all P-K Screws, other useful data. Ask for Form 600A.



*A. S. A. Designation — Type B

When you have planned assembly savings, make sure they *pay off* on the assembly line by specifying *P-K* Self-tapping Screws. The originator and largest manufacturer, Parker-Kalon has learned through long experience how to provide the proper combination of hardness and toughness, the sharp threads and accurate size, the consistent dependability that avoids spoiled parts and keeps assembly trouble-free.

Try P-K Screws. You'll agree "If it's P-K, it's O.K." Parker-Kalon Division, General American Transportation Corporation, Clifton, N. J.

specify P-K to be sure PLANNED SAVINGS WILL PAY OFF

the molder was blamed

When "tough breaks" like this occur, the custom molder is usually blamed. But the fault was in choosing the wrong type of fastener. That's why so many molders get recommendations *first* from Parker-Kalon.

Type F	Type U
ALSO MADE WITH PHILLIPS HEAD	
Primarily used for fastenings in crumbly and friable materials, in phenolic and urea base compounds, cold mold compositions, and hard rubber. Cuts thread as it is turned in. Can be removed and replaced.	For permanent fastenings. A hardened drive screw, it is hammered or pressed in, forming its own thread. Suitable for all types of plastics. Can be driven rapidly with hopper-fed machines. Cannot be removed.
Standard screws are hardened steel, available with any plated or other finishes in common use. Furnished on special order in Type 410 corrosion resistant Steel, hardened.	Standard screws are hardened steel, available with any plated or other finishes in common use. Furnished on special order in Type 410 corrosion resistant Steel, hardened.
Standard head styles are Round, Binding, Flat, Oval, and Hex.	Standard head style is Round only. Other head styles on special order.
(illust.) Non-standard forms of Type F can be developed and furnished to order. Typical modifications are illustrated.	(illust.) Non-standard forms of Type U can be developed and furnished to special order. Typical modifications are illustrated.

P-K Self-tapping Screws are used in thousands of the nation's best-known products for fastenings to the following plastics:

PHENOL FORMALDEHYDE
Molded: Bakelite, Durez, etc.
Cast: Catalyn, etc.
Laminated: Formica, Textolite, etc.

UREA FORMALDEHYDE
Molded: Plaskon, Beetle, etc.

CELLULOSE ACETATES & CELLULOSE NITRATES:
Tenite, Lumarith, Plastacele, Celluloid, Pyralin, etc.

ACRYLATE and STYRENE RESINS:
Lucite, Plexiglas, Styron, etc.

PLYWOOD, Resin Impregnated
Compreg, Pregwood, etc.

IF IT'S P-K IT'S O.K.

P-K Users' Guide
Plastic bound, index-tabbed work-book of technical information on selection and application of P-K Screws. Popular with designers and engineers, and draftsmen for quick reference. Ask for Form 479C.

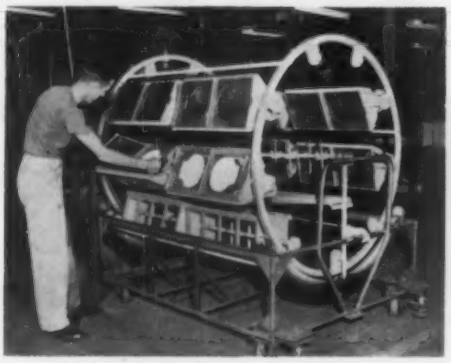
Get Started Easily

IN VACUUM COATING

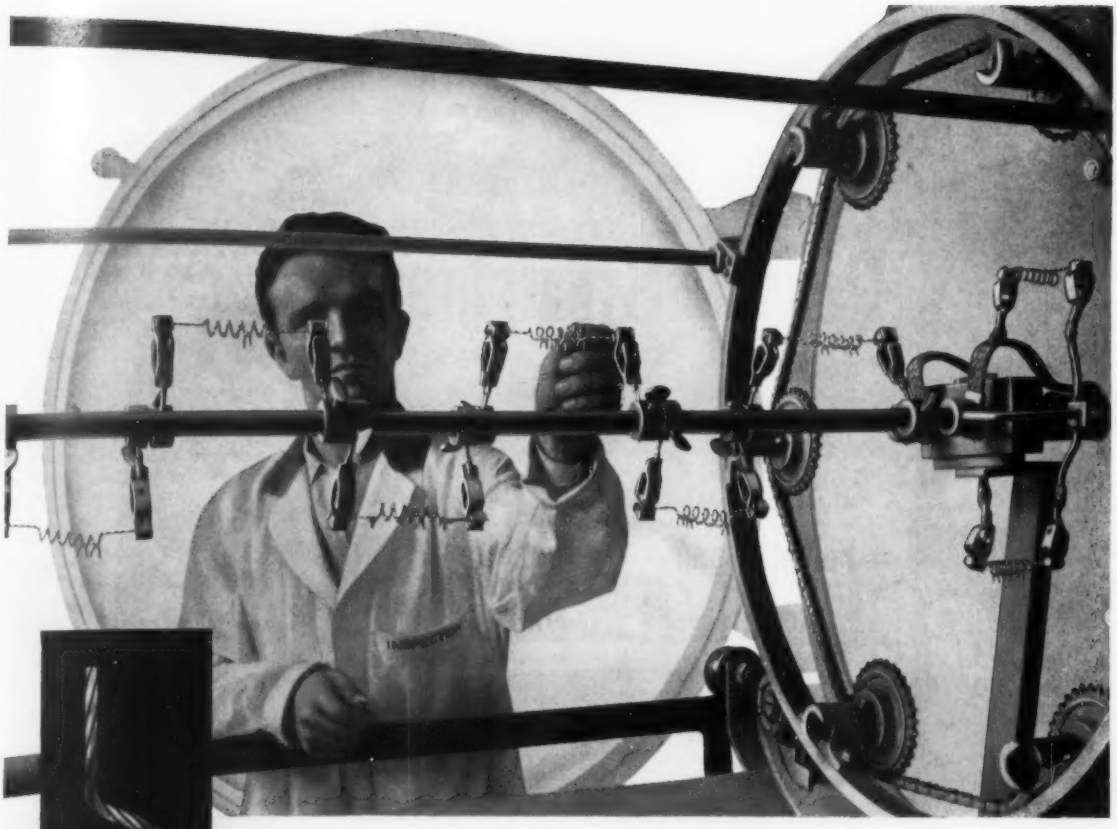


Vacuum coating can help you open up new markets by adding a quality appearance to your products. Brilliant metallic finishes can be applied in a wide range of colors at surprisingly low cost.

Today's vacuum coatings are brighter than buffed and polished electroplating, cost less, and in some applications, stand up better.

Send us a sample of your product and give us details about its use. We'll tell you whether your application is a good one, show you how your product will look, and estimate your operating costs. We can supply a complete installation, guarantee its output, and train your operators. Write us today!

A wide variety of products and materials can be coated economically with unmatched beauty.



High Quality, easy loading, and short cycle time are possible through advanced high vacuum engineering.

Looking for more "shots per dollar" in vacuum metallizing coils?

By switching to the best coil design, vacuum metallizers have realized as much as 30% more shots per dollar from Sylvania Tungsten Coils. Why is this possible? Because Sylvania helps vacuum metallizers find the right coil to do their job most economically. Whether you buy ready-made coils or form your own from tungsten strand, Sylvania is ready to help you get maximum efficiency.

If your metallizing process calls for a custom-made coil, Sylvania can recommend the best design consistent with the equipment you're using and the metallizing job to be done. In many cases, metallizers can get top efficiency from an existing Sylvania design, many of which have already become so popular they are considered standard.

Sylvania coils are formed of high-density tungsten strand manufactured to exacting standards of quality control. Sylvania Tungsten Strand is available in 3 to 7 ply with wire diameters of 0.020 to 0.600 inches per strand.

We invite you to write, outlining your specific requirements and problems. You'll find Sylvania is your best source for vacuum metallizing coils designed and built to offer "more shots per dollar."

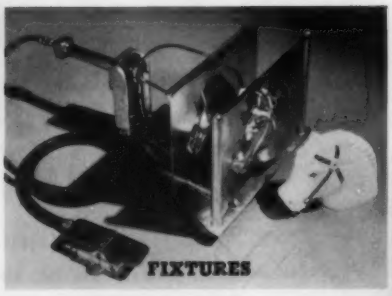
AUTOMATIC MACHINES

Manufacturers of all the equipment needed to equip you with the most practical system for handling your particular projects most efficiently.

A trained engineering staff familiar with all types of materials, translucents, teflon and metallics, and with knowledge of die casting, stamping and plastic molding procedures as they relate to high production spray finishing.



AUTOMATIC MACHINES—Standard and special automatic and semi-automatic machines for decorating parts of all sizes and shapes. High production with small investment. Skilled operators unnecessary. Automatic clamping and ejection of parts. Adjustable sequence-type operation. Hydraulic two-fluid control system maintains accurate repeats and eliminates cost of explosion-proof controls. Paint in one or two directions. Steady, hydraulic controlled gun movement.

MASK WASHING MACHINES—The fastest, really efficient, explosion-proof automatic mask washers. Increase production with fewer tools. Eliminate damage and costly repairs of masks. Lowest solvent consumption. High pressure, no-leak pump.

FIXTURES—Mechanical and air operated clamps and pressure fixtures for holding masks and parts. Special and standard fixtures speed up production, assure highest quality work. Horizontal: adjustable to masks 3" to 36". Vertical: revolve 360°. Square shaft registering air piston. Ejectors prevent distorted parts or parts from different cavities from sticking in mask. Double Acting: apply pressure to both sides of parts to be painted on two or more sides with one masking.

MASKS—Electro-formed nickel or copper masks of all types for shielding and spraying highly intricate areas in single or multiple colors. Permit more shots between washings. Allow for reasonable dimensional differences in piece parts. Finger clearance affords easier loading of parts. Right hand tab masks free both hands for productive movements.

FIXTURES

Send prints or sample parts, giving production requirements and results you wish to achieve.

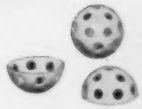
NOW YOU CAN

HEAT SEAL

MOLDED PLASTIC* PARTS

* POLYETHYLENE and OTHER THERMOPLASTIC PARTS

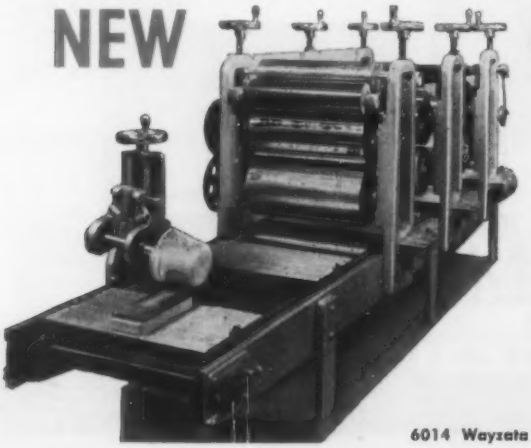


The Cosomatic Sealer automatically and without the use of adhesives, seals polyethylene parts on a production basis. This is the first commercially practical machine available for heat sealing molded polyethylene parts. It has been released after eleven years of development and nine years of actual use in product manufacture. Both the process and machine are covered by United States and foreign patents. WRITE TODAY FOR COMPLETE INFORMATION.

COSOMATIC SEALER

- Completely automatic sealing cycle.
- Accommodates a wide variety of shapes and sizes of hollow molded parts.
- Opens a new field of applications for polyethylene.
- Ideal for sealing toys, sporting goods, domestic and chemical containers, housewares and special industrial housings.

Two examples of products sealed using Cosomatic Sealer . . .



PGB Golf Ball—over 9 million have been sold. (Sealed ball and 2 halves shown.)

Bowlite Bowling Pin Note Intricate Shape.

NEW COSOMATIC PRESS

Prints plastic items faster—better—at lower cost!

- Eliminates decals, hot stamping and slow, expensive silk screening.

Print plastic items never before possible. The Cosomatic Press prints either letterpress or offset—on *three* different levels—up to *three* different colors simultaneously! Flat, round, tapered raised, or recessed faces can be printed in production or short runs, quickly, economically. Used by leading plastic product makers throughout the United States.

HOPP

Pioneer in Plastics

SUPPLIES YOUR EVERY NEED...

with more than 64 years of experience. Known as the leader in this field . . . Hopp has developed unique methods of plastic printing. Hopp has kept pace with industries demands . . . and is able to offer, under one roof, facilities that meet your needs, help solve your problems, and above all . . . save you valuable time and money. Among the diversified facilities are:

★ **PLASTIC PRINTING:** Simple though it sounds, printing on plastics requires years of tireless experimentation to perfect. Special inks and methods, universally used today, were developed, we are proud to say, in our own plant.

★ **PLASTIC LAMINATING:** Using the heat and pressure method of hydraulic pressure lamination exclusively the printed surface is under a protective layer of transparent plastic.

★ **PLASTIC FABRICATING:** Our Fabricating departments are equipped to fabricate printed or unprinted plastic sheetings and perform such operations as die-cutting, bending, numbering, punching, forming, embossing, stamping, shearing, sawing, drilling, cementing, etc.

★ **INJECTION MOLDING:** Making our own dies and molds in our own completely equipped tool rooms.

★ **METAL FABRICATING:** Combining with plastic, makes Hopp an ideal source of supply. Hopp's equipment includes metal rolling, punching, framing, baking, etc.

WHATEVER YOUR REQUIREMENTS IN PLASTICS . . . CONSULT HOPP . . . PIONEER IN PLASTICS SINCE 1893

CHECK THREE WAYS *to get more value out of advertising to packagers!*

✓ 1 CHECK THE CIRCULATION of packaging magazines: MODERN PACKAGING has the largest paid circulation in the field . . . and what's more, packagers are willing to pay a big $7 a year for it, at that!

Why is paid circulation so important?

Because of the intricate purchasing patterns involved in the selection and specification of containers, packaging materials and equipment, it's not possible to select "packaging men" simply on the basis of job titles.

For this reason, MODERN PACKAGING's policy of *paid circulation* is vitally important to advertisers. It is insurance that the magazine's readers are directly and intimately concerned with packaging operations: they've *vouched for themselves and their interests* by laying hard cash on the line. Most significantly, this paid circulation keeps climbing to match the rapid growth of the field year after year . . . climbing 40% in the past five years!

As the one magazine in the field with paid, ABC-audited circulation – and a high renewal rate of 72% – MODERN PACKAGING gives advertisers assurance of interested readers . . . interested in *packaging!*

✓ 2 CHECK THE EDITORIAL EFFECTIVENESS of packaging magazines: Since 1952, seven independent surveys* show that MODERN PACKAGING is *read* and *preferred* by more men-who-specify-and-buy-for-packaging than any other magazine in the field!

And the reason is plain:

The editorial purpose of MODERN PACKAGING is to keep packagers informed of all the significant advances in packaging methods, materials and equipment. Editorial feature space is devoted to carefully researched original articles. About 90% is staff written, 10% contributed by authorities in the field. Through the use of analyses, illustrations, case histories and "how-to-do-it" articles, the editors point out and interpret packaging trends.

The Technical Section, dealing with physical and chemical problems and developments in the field, is considered as the Number One reference text of packaging engineers and technicians.

New design developments in packaging and packaging display are regularly covered by the pictorial features: "Packaging Pageant," "Design History" and "Display Gallery."

Other closely read editorial departments are: "Equipment and Materials," "Plants and People," and "U. S. Patents Digest."

In short, MODERN PACKAGING is *read* and *preferred* for its authoritative editorial coverage of new materials and equipment, packaging trends, and for its comprehensive technical data on materials and production!

✓ 3 CHECK THE ACCEPTANCE BY ADVERTISERS of packaging magazines: Year after year, more advertisers invest more money in more space in MODERN PACKAGING than in *all other packaging publications combined.* And last year they spent more dollars for more space in MODERN PACKAGING than ever before! Most of them *keep* using its pages year after year–almost 60% are 5-to-25-year-old advertisers in MODERN PACKAGING!

Who are these advertisers? They are manufacturers of packaging *materials and supplies*, including:

Adhesives, coatings, cork, fabric, film, foil, glass, ink, wood, paper, plastics, rubber, tape and wax.

And MODERN PACKAGING advertisers also include makers of *containers*, such as:

Bags, bottles, boxes, cans, cartons, chests, crates, capsules, drums, envelopes, jars, tubes, vials and wrappers.

Other MODERN PACKAGING advertisers sell such *machinery and equipment* as:

Bag machines, bottling equipment, box machines, capping equipment, cartoners, conveyors, counters, die-cutters, filling machines, labelers, printing presses, scales, slitters, staplers, stitchers, unscramblers and vibrators.

And included among MODERN PACKAGING advertisers are companies offering such *services* as:

Designing, embossing, fabricating, laminating, plastic molding, and contract packaging.

**Write for the full reports of all 7 surveys. For further information on the market and the magazine, ask for the 44-page data book, "The Packaging Field . . . and How to Reach It," and for the booklets, "Let's Take the Measure," and "Basic Editorial Policies."*

MODERN PACKAGING ENCYCLOPEDIA ISSUE

Published annually in November, it's the standard workbook of the nation's packaging men . . . a complete encyclopedia of packaging materials, equipment and methodology. Last year's issue ran to 834 pages . . . covered all phases of packaging design and production. Closing date: August 2nd.

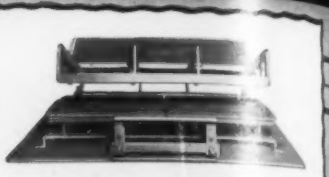
MODERN PACKAGING

A BRESKIN PUBLICATION

575 Madison Avenue, New York 22, N. Y.



HIGH SPEED OPERATION

Four Sequence photos illustrate the following: 1) Loading mask into fixture. 2) Placing part in mask. 3) Closed fixture — Actuate air cylinder. 4) Fixture, mask and part in spray position.

Illustration shows a very delicate spray mask incorporating over 100 individual suspended characters on .040 diameter music wire bridges.

Two-tone air conditioning grille — mask and fixture adaptable to various size grilles.

Mask and part illustrating one of many typical applications for masking.

YOUR spray mask finishing problem from blue print to complete production tooling — We serve in the following capacity: CONSULTANTS for proper parts design to achieve lower cost and peak efficiency in your finishing department. ENGINEERS for the most modern methods of production spray mask painting techniques. DESIGNERS of spray masks, jigs, and fixtures, mechanical and air-operated. MANUFACTURERS of nickel electro-formed spray masks, jigs, and fixtures.

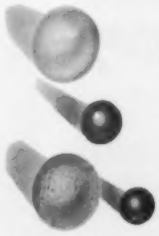
Designed and Built for Special Mask Finishing Applications

STANDARD MODEL 5-M



Complete versatility for almost any small parts.

Available in 6 spray-gun combinations (stationary and up to 4 oscillating guns).

Other features available for special applications.

BALLS UNLIMITED

FOR UNLIMITED APPLICATIONS

We specialize in the manufacture of precision balls in desired diameters made from non-metallic materials including.

ACETATE BUTYRATE POLYSTYRENE
NYLON TEFLON LUCITE EPOXY
STYROFOAM WOOD CORK FIBER

Remember, only a *ball* does the *job of a ball.*

So consider a ball for your purpose—and consider the job well done by ORANGE PRODUCTS.

Small turnings of cylindrical shapes formed from round rods and tubes for all types of applications.

Range of sizes is from ⅛" to 1" diameter and up to 7" long. We hold tolerances of .002 on plastic and .005 on wood, plus or minus.

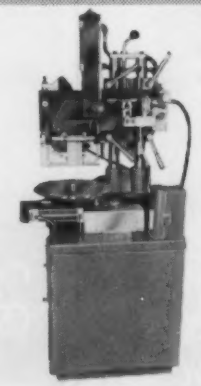
HOT STAMPING PRESSES *in a* COMPLETE RANGE

The BUILDER MODEL KWIKPRINT

is one of 4 hand operated models of which there are thousands in daily use on small as well as production runs. Has an automatic roll leaf attachment and tiltable typeholder for quick changes of type or dies.



KENSOL 50 ROLL LEAF STAMPING PRESS

This is the latest type extra heavy duty high speed, double toggle press, air operated with electric dwell timer, thermostat, with 9 x 12" head and automatic roll leaf attachment. Head size 6 x 9 and larger than 9 x 12 equipped with criss cross roll leaf attachment also available. This is only one of several Kensol models in hand or air operated machines.

PEERLESS MODEL G HEAVY DUTY TOGGLE ACTION AIR OPERATED STAMPING PRESS

Illustration shows dial table, but can also be had with slide table, both air operated and synchronized with head. Has deep throat, adjustable head up to 6" maximum day light, with assorted head and chase sizes, bulky 2¼" posts, deep set in base casting for rigid support, air operated roll feed attachment, etc. Only one of several Peerless models for hand and air operation.

Plus

a complete line of roll feed attachments — hot plates — stamping foils in ALL colors — rubber dies — die mount — jigs and fixtures — brass and steel type — etc.

anything in plastics can be finished better with Anchor Specialized Dial Coatings

Our specialization in Dial Finishes over many years has earned a reputation for quality in products and results.

These two products are cutting finishing time and costs for leading plastics fabricators.

Anchor Plastic Lacquers are extensively used both as a back up paint and an overall finish on dials. Rapid drying, excellent build and hiding, perfect adhesion and color retention. Made to fit the specific requirements of the plastic for which it is used.

Anchor Dial Filler dry-wipes in minutes. Won't streak, produces a clean, sharp opaque color with a minimum of time and labor. May be applied by brush, roller, squeezer or spray. In colors to meet your color standards.

These two specialized products are being used by many of the nation's largest manufacturers. You can use them with confidence.

Accurate "identical twin" tracing is accomplished through the Contourmaster's hydraulic automatic depth control unit

Identical Twins

. . .but One is a Low-Cost Contourmaster Reproduction of the Other

CINCINNATI CONTOURMASTER MILLING MACHINE
Catalog No. M-1919-2

Exact copy milling cuts hand finishing time; reduces cost to the bare essentials. Exact copy milling, and the low cost that goes with it, can be taken for granted when you assign your mold, die and hob work to CINCINNATI® Contourmaster Milling Machines. ¶ Contourmasters are equipped with sensitive hydraulic automatic depth control which automatically and accurately scans the vertical profile of the master. The cutter spindle follows the same path, producing an identical twin in metal. ¶ Other machining operations required to finish the mold can also be handled on Contourmasters. The spindle head can be swiveled forward and back; the table traverses 16" or 22"; cross traverse 10"; Shaping Attachment can be mounted on the ram and swiveled to position over the table when needed. Contourmasters are the finest tool and die milling machines for your shop. Write for catalog No. M-1919-2. Brief specifications in Sweet's Machine Tool File.

M-3 IMS M-4 GRANULATORS

All machines illustrated here in stock for prompt delivery.

The IMS M-3 6½" x 7" throat sprue grinder — rugged — simple in design — easiest to clean — built-in throat clearance bar — casters — catch pan.

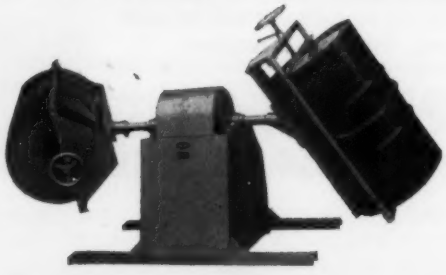
PRICE: Complete with 1 HP Motor and Starter $598.50

The IMS M-4 5⅜" x 8½" throat grinder — designed primarily for vinyl, polyethylene, plastisols and all elastomerics where a fine-free low bulk factor product is desired — large throat for large injection molded parts.

PRICE: Complete with 2 HP Motor and Starter $788.50
Same, but with 3 HP Motor $854.00

CONSTANT MOLD TEMPERATURE REGULATOR

The IMS Economy Circulator — **priced at only $369.50 complete (oil model for heats to 450° at $482.50)** — duplicates performance of mold heaters costing up to 6 times as much — developed by a molder for molders — compact — portable only 15" x 22½" floor space.



NOTE: Special price for 2 units ..... $349.50 Each

Send for our 1957 Nozzle Catalog and Heater Band Book Today. You'll find all styles of nozzles and heater bands fully described and priced, with technical notes on nylon molding.

Prompt service on all kinds of nozzles by the world's largest and most experienced nozzle specialists.

IMS DRUM TUMBLERS

FOR ALL COLORING AND MIXING OPERATIONS

All IMS Drum Tumblers are based on design suggestions of the leading material and colorant suppliers. Available for immediate shipment from stock.

¾ HP Model **$595.00**
(Takes drums up to 33" high x 22" in diam.)
2 HP Model **$897.50**
(Takes drums up to 37" high x 23¼" in diam.)
3 HP Model **$1285.00**
(Takes drums up to 45" high x 24" in diam.)

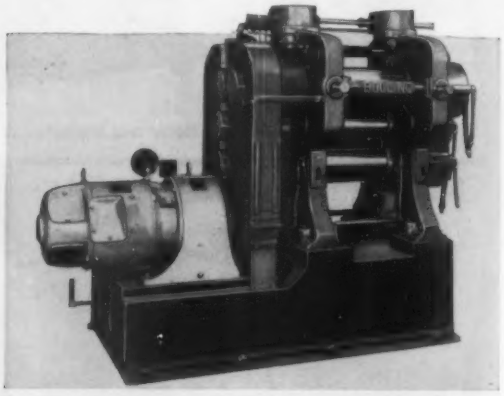
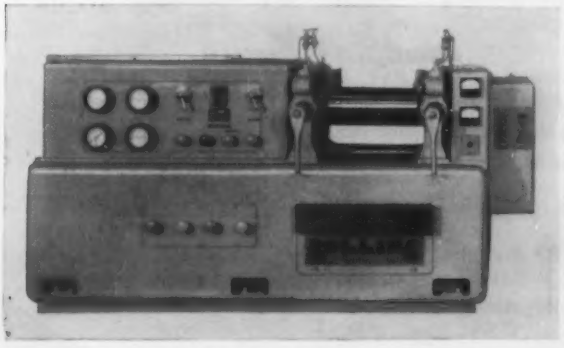
PRODUCTION and LABORATORY MACHINERY

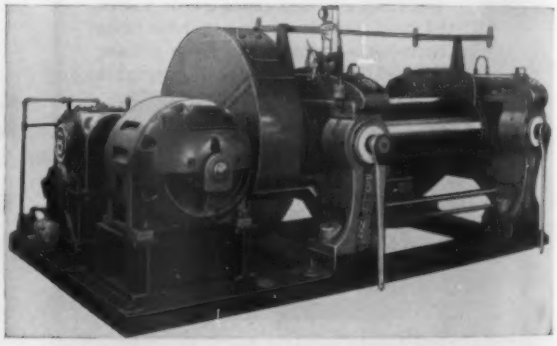
PLASTICS • RUBBER



Have you investigated the wide scope of Stewart Bolling equipment? . . . Bolling *intensive mixers* embody exclusive Spiral-Flow removable side construction. The new compound drive, illustrated at the right, permits speeds and power heretofore not attained on any other mixer. . . *Presses* are made in many sizes and types, signifying an experience unparalleled in this field. . . . A broad range of roll sizes and frame designs is offered in the Bolling line of *calenders*. . . Today's largest line of *laboratory mills* is found at Bolling because of our pioneering and specializing in this restricted but crucial phase of production. Bolling *production mills* have long since established themselves as featuring operating convenience and safety with minimum maintenance. . . A catalog on each basic line of equipment will be sent upon your letterhead request.



MIXERS *Above is No. 10 with compound drive. Six sizes from 231 to 16000 cu. in. chamber capacities offered.*



PRESSES *Transfer and compression molding presses from 50 to 2500 tons, 14" x 14" through 42" x 42".*

CALENDERS *Above is 4-roll, 8" x 16" lab-production model. 2-, 3- and 4-roll from 8" dia. through 22" dia. rolls, 16" through 66" face.*

MILLS *Above left is an 8" x 20" deluxe laboratory model. Right above is a 22" x 60" production size. Eleven sizes from 2½" dia., 7" wide rolls, through 26" dia., 100" width.*

NRM Thermoplastics EXTRUDERS

offer the plastics industry

advanced design, construction and operating features like these . . .

1. ***BALANCED HEAT CONTROL—***
This patented NRM feature assures the *uniform* heating which results in closer-tolerance extrusions of finer finish and shape holding quality.

2. ***"CAST IN" CYLINDER HEATING—***
The aluminum body of the heater is cast around the heating element, enclosing it completely. Possibility of any kind of failure is virtually eliminated. In addition to longer life, they offer quicker response to controls than other types of cylinder heaters.

3. ***AUTOMATIC DIE HEAD CLAMPS—***
Air (or hydraulic) cylinders *instantly* lock the die head, making a leak-proof seal . . . or as quickly release it to speed up cleaning or die and screen changing on large NRM Extruders (6" to 15").

4. ***20:1 RATIO ONE-PIECE CYLINDERS—***
With effective cylinder and screw lengths twenty times their diameter, more intensive heating and greater mechanical working of the plastic is provided. Results are top quality extrusions produced with less waste 30 to 50% faster than with extruders having shorter cylinders.

5. ***SINGLE-WALL XALOY CYLINDER LINING—***
For more compact, more durable extruder construction. Corrosion-resistant Xaloy 306 assures long cylinder life with original dimensions maintained.

6. ***JOB DESIGNED FEED SCREWS—***
NRM patented Torpedo Screws improve both quantity and quality of plastics production by thorough mixing, evenly distributing heat through the compound, and by obtaining uniform cross-sectional pressure at the die. NRM has a screw type to meet all extruding requirements.

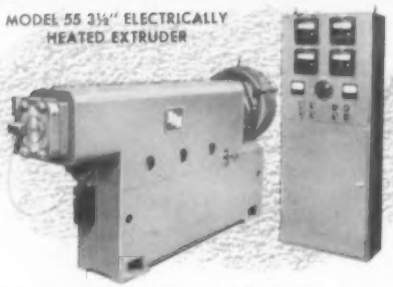
7. ***J.I.C. CODED ELECTRIC CONTROL CABINETS—***
Precision-engineered and quality-constructed, giving you wiring to a universal standard, labeled circuits, and all wiring completed to terminals. J.I.C. Control Cabinets are Standard NRM equipment.

8. ***MATCHED DIES AND ACCESSORIES—***
NRM makes available dies and haul-off equipment designed specially for the type of extrusion, and to utilize to the fullest, the high production capacities of NRM Extruders.

THERE'S AN NRM WITH DIES AND ACCESSORIES TO HANDLE EVERY EXTRUDING REQUIREMENT . . .

From small 1" Laboratory Bench Models to big 15" high-capacity Extruders with Automatic Die Head Clamps, *all* have the same quality features that make NRM Extruders most profitable to operate, and which *sustain* profitable operation over many years of trouble-free service. The Extruders and equipment shown below and on following pages are representative only of the NRM *full* line. Check them over and contact us for more details today. There's an NRM of the right type and size to handle every extruding requirement.

NRM MODEL 55 2-1/2" EXTRUDERS



NOMINAL CAPACITY: 80-115 lbs./hour—SCREW SPEED: 11-72 rpm. Minimum Range—DRIVE: 15 hp—REDUCTION UNIT: Cone Worm Gear—15:1 Ratio—FLOOR SPACE: 89⅞" long x 25" wide (Extruder only), 22" deep x 38" wide (Control Cabinet), 38" long x 27½" wide (Oil Heating Unit)

	Electric	Oil	Steam
Max. Operating Temperatures:	650°F	575°F	250 psi
Temperature Controls:	Proportioning Pyrometer	Electric & Manual Control	None Furnished

NRM 2½" ELECTRICALLY HEATED EXTRUDER WITH OFFSET PIPE DIE

NRM MODEL 55 3-1/2" EXTRUDERS

MODEL 55 3½" ELECTRICALLY HEATED EXTRUDER

NOMINAL CAPACITY: 160-230 lbs./hour—SCREW SPEED: 12-73 rpm, Minimum Range—DRIVE: 25 hp—REDUCTION UNIT: Herringbone Gear—24.5:1 Ratio—FLOOR SPACE: 112" long x 36" wide (Extruder only), 22" deep x 38" wide (Control Cabinet) 38" long x 27½" wide (Oil Heating Unit)

	Electric	Oil	Steam
Max. Operating Temperatures:	650°F	575°F	250 psi
Temperature Controls:	Proportioning Pyrometer	Electric & Manual Control	None Furnished

NRM MODEL 55 6" EXTRUDERS

MODEL 55 6" ELECTRICALLY HEATED EXTRUDER

NOMINAL CAPACITY: 450-675 lbs./hour—SCREW SPEED: 6-72 rpm, Minimum Range—DRIVE: 100 hp—REDUCTION UNIT: Herringbone Gear—24.5:1 Ratio—FLOOR SPACE: 177" long x 48" wide (Extruder only), 22" deep x 38" wide (Control Cabinet), 38" long x 27½" wide (Oil Heating Unit—3 req'd)

	Electric	Oil	Steam
Max. Operating Temperatures:	650°F	575°F	250 psi
Temperature Controls:	Proportioning Pyrometer	Electric & Manual Control	None Furnished

NRM MODEL 55 1-1/2" EXTRUDERS

NOMINAL CAPACITY: 30-35 lbs./hour—SCREW SPEED: 10-71 rpm — DRIVE: 3 hp — REDUCTION: Chain Drive—FLOOR SPACE: 49" long x 19" wide (Extruder with Drive). 10" deep x 20" wide (Control Cabinet)—MAX. OPERATING TEMPERATURE: 650°F—TEMPERATURE CONTROLS: Proportioning Pyrometer Type.

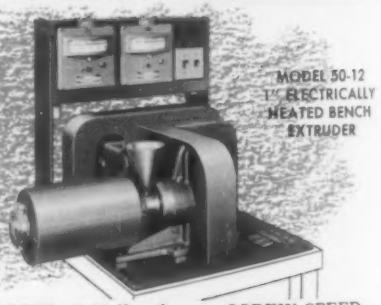
1½" ELECTRICALLY HEATED 20:1 Le/D RATIO EXTRUDER

NRM MODEL 55 4-1/2" EXTRUDERS

MODEL 55 4½" ELECTRICALLY HEATED EXTRUDER

NOMINAL CAPACITY: 275-375 lbs./hour—SCREW SPEED: 9-75 rpm, Minimum Range—DRIVE: 50 hp—REDUCTION UNIT: Herringbone Gear—24.5:1 Ratio—FLOOR SPACE: 143" long x 39" wide (Extruder only), 22" deep x 38" wide (Control Cabinet), 38" long x 27½" wide (Oil Heating Unit—2 req'd)

	Electric	Oil	Steam
Max. Operating Temperatures:	650°F	575°F	250 psi
Temperature Controls:	Proportioning Pyrometer	Electric & Manual Control	None Furnished



NRM SPECIAL 8" EXTRUDER

This 8" Electrically Heated Extruder is typical of how NRM can incorporate in a single machine, standard proven design features to obtain a "custom" installation. This *standard* Extruder has Automatic Die Clamp, special screw and special electrically heated cable covering crosshead.

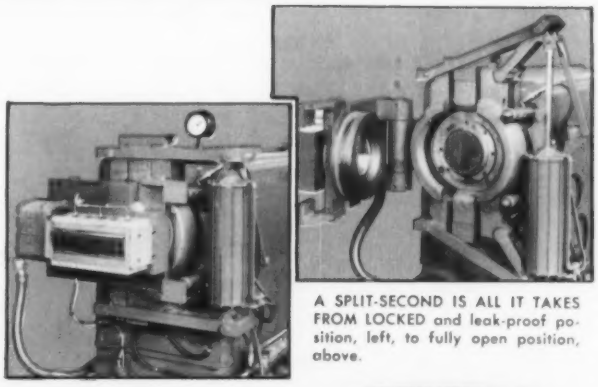
NRM 1" BENCH MODEL EXTRUDERS

For Laboratory and Light Production Work

MODEL 50-12 1" ELECTRICALLY HEATED BENCH EXTRUDER

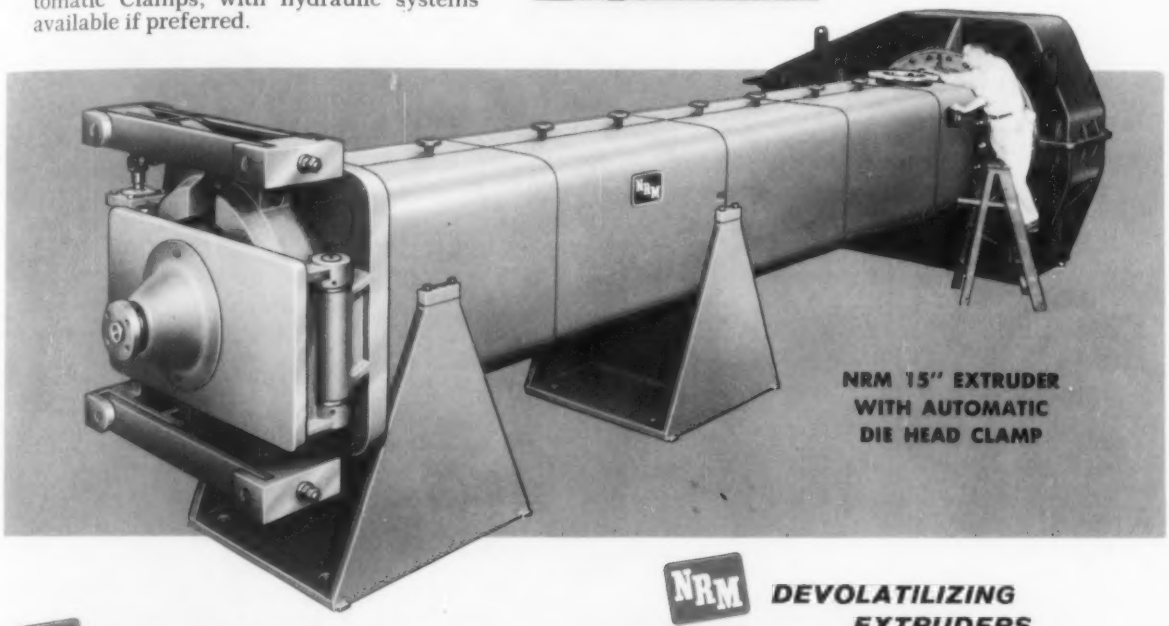
NOMINAL CAPACITY: 6-10 lbs./hour—SCREW SPEED: 21-136 rpm—DRIVE: ¾ hp Variable Speed—REDUCTION UNIT: Combination Gears and Belts—BENCH SPACE: 34⅞" long x 27" wide.

	Electric	Oil
Max. Operating Temperatures:	650°F	575°F
Temperature Controls:	Proportioning Pyrometer Thermostatic	



EXTRUDERS WITH *AUTOMATIC* DIE HEAD CLAMPS

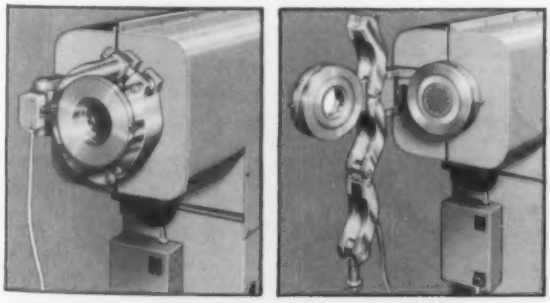
The latest engineering refinement contributing to easier and faster operation of large NRM Extruders (6″ to 15″) is the Automatic Die Head Clamp. Touching a lever *instantly* locks the head with a positively leak-proof seal, or as quickly unlocks it for quick screen changing or cleaning. In addition to time and labor saving features, other advantages of the Automatic Clamp are:



POSITIVE SEALING—no leakage of material around the head.

FOOLPROOF ACTION — simplicity and compactness makes it completely dependable.

PNEUMATIC CYLINDERS power the Automatic Clamps, with hydraulic systems available if preferred.



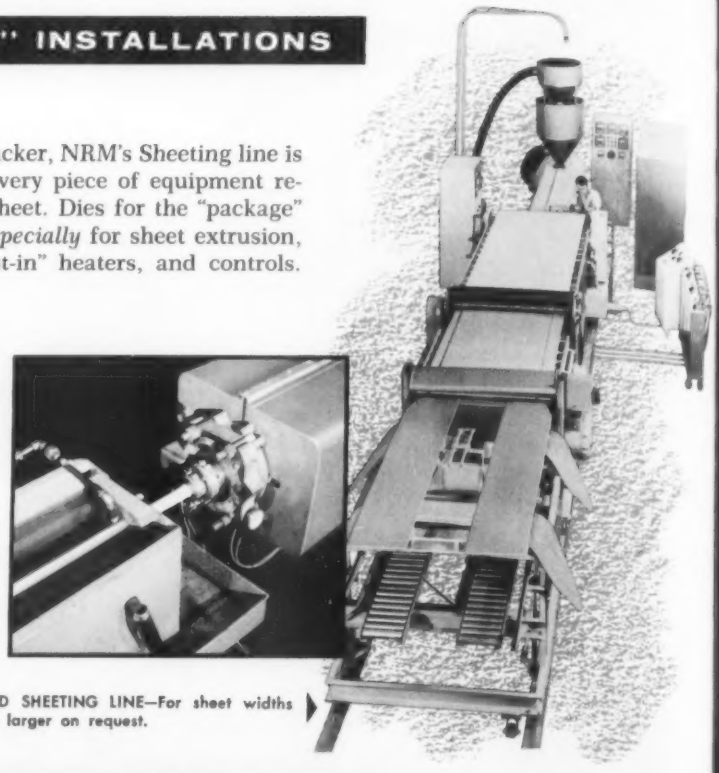
A SPLIT-SECOND IS ALL IT TAKES FROM LOCKED and leak-proof position, left, to fully open position, above.

NRM 15″ EXTRUDER WITH AUTOMATIC DIE HEAD CLAMP

EXTRUDERS WITH "HANDY CLAMP DIE HEADS"

Manually operated "clamp-type" die heads are available for 1½″, 2½″, 3½″ and 4½″ NRM Extruders on request. From leak-proof closed and locked position (left) they may be unlocked and opened (right) by loosening the single swing bolt shown. Note the rugged construction.

DEVOLATILIZING EXTRUDERS



NRM 4½″ DEVOLATILIZING EXTRUDER

These Extruders make use of a special patented, adjustable valve, and a large vent to remove moisture and gases from plastics which must be vented to prevent porosity. Typical are cellulose, acetate and butyrate, ethyl cellulose acrylic and vinyl pellet and powder blends . . . especially when used for wire covering. They are obtainable in all sizes and may be electric, oil or steam heated.

NRM "PACKAGED" INSTALLATIONS

FOR RIGID SHEET—From Extruder to stacker, NRM's Sheeting line is a self-contained unit which includes every piece of equipment required for production of rigid plastic sheet. Dies for the "package" are extremely rugged, are engineered *specially* for sheet extrusion, and are furnished complete with "cast-in" heaters, and controls. Write for full details.

FOR PLASTIC PIPE — Standard Units consist of Extruder, Die, Cooling Tank, Take-up, Cut-off, and/or Wind-up. Complete unit not shown. Write for full details.

NRM RIGID SHEETING LINE—For sheet widths up to 48", larger on request.

NRM DIES AND ACCESSORIES

VERTICAL TUBING DIES
Size range: 1" to 12" inclusive, for extrusion of blown P.V.C. and Polyethylene film.

ANNULAR TUBING DIES
Size range: 14" to 36", other sizes on request, for extrusion of large blown film tubing.

PIPE DIES
Size range: ½" to 6" I.P.S. Straight delivery and offset types available for extrusion of rigid P.V.C., Polyethylene, Acetate Butyrate and Kralastic pipe.

TEE-TYPE DIES
Size range: 12" to 96", for extrusion of flat Polyethylene film and Polyethylene laminating.

SHEETING DIES
Size range: 24" to 48" widths, gauges, .040" to .180, other sizes and gauges on request. Three styles available for extrusion of Acrylic, high impact Polystyrene, Acetate, Acetate Butyrate, Kralastic, Polyethylene and P.V.C., rigid and elastomeric.

NRM ACCESSORIES include Conveyors, Cooling Tanks, Pipe Haul-Offs, Blown Film Take-ups, and others. Write for details.

WRITE TODAY
for more details, quotations, demonstrations or engineering assistance. Our extensive laboratory facilities are available to help solve your extrusion problems.

OTHER SIZES FOR ALL DIES AVAILABLE ON REQUEST

Sterlco® TEMPERATURE CONTROL UNITS

THE LOGICAL CHOICE OF EQUIPMENT MANUFACTURERS, MATERIAL SUPPLIERS and PLASTICS PROCESSORS for FASTER PRODUCTION, FINER PRODUCTS and FEWER REJECTS

MODEL 6002

The DUAL mobile temperature control unit functioning in leading plastics plants from coast to coast. Ready to operate when connected to electricity, water, and drain.

MODEL 6003

A compact DUAL unit designed for permanent installations. (Can be equipped with casters.) Requires less floor space than Model 6002 with some capacities.

MODEL 6012

A compact, efficient SINGLE unit designed to do the typical Sterlco job of temperature control where a single stabilized temperature is adequate. Can be combined with Sterlco Model 6002 and 6003 Dual units where more than two temperatures are required.

only Sterlco® offers

- Super-fast 9000 watt heating units for quick starts.
- Small total water capacity, — no excess thermal carryover either way.
- Super-sensitive, accurate *heating control* with extremely fast reaction time.
- Flexible, modulating *cooling control* — not on or off.

MODEL 6007

HIGH TEMPERATURE DUAL OIL CIRCULATING UNIT — The Model 6007 assures accurate control from 100° to 500° F. The Model 6007 is a dual unit, affording interchangeable double capacity for all applications where steady, accurate high temperature control is necessary.

MODEL 6016—HIGH TEMPERATURE SINGLE OIL CIRCULATING UNIT — A compact SINGLE unit with the same basic features as Model 6007 plus choice of heater capacity.

MODEL 6031

TRIPLE TEMPERATURE CONTROL UNIT — This unit was specially designed for use in the manufacture of plastic sheet. It provides accurate temperature control for molds and rolls with provision for temperatures up to 240° F.

Sterlco Engineers are always available to assist you in the selection of proper temperature control equipment . . . write today!

MODEL 7000

COOLING AND CIRCULATING UNIT— *Where cooling only is required.* This unit accurately and automatically does the work without any guesswork and without wasteful "on and off" valves. Same operating features as Models 6002, 6003, and 6012 but without provision for heating. Excellent for use at sprue section of large molds.

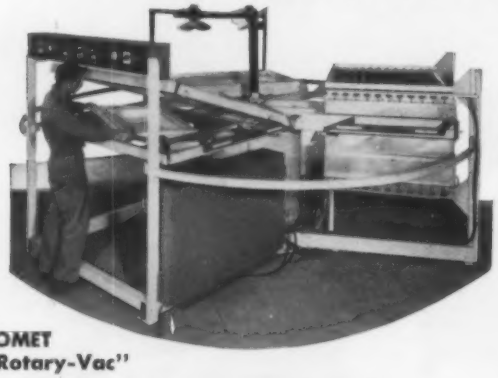
. . . with a "Comet" PLASTIC SHEET FORMING MACHINE



COMET "Twin"

Two complete and individually controlled Drape and Vacuum Forming Machines built into a common frame using one vacuum source and heating unit. This construction and design has resulted in the utmost in productivity and reduced costs. A real leader in the industry.

COMET "Star"

New Forming Techniques incorporated into one machine for the first time: **Snapback Forming—Mechanical Forming—Pressure Forming—Airslip Forming—Vacuum Forming and Trimming in One Operation.** Counteracting platens have positive control of Plastic Sheet during forming operations. Available in 4 sizes with either single or double forming press.

COMET "Rotary-Vac"

VACUUM, DRAPE AND AIRSLIP FORMING
200% GREATER PRODUCTION—Operator Loads and Unloads at One Station—All Other Operations Fully Automatic.

- Fast and easy to set-up.
- Enclosed oven with heating from 2 sides.
- Safe—simple to operate.
- Rugged and dependable construction.
- Stroke 17".

ALSO AVAILABLE WITH MALE ASSIST.

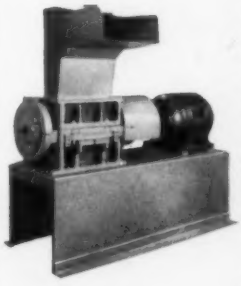
FRANKLIN PARK, ILLINOIS, U.S.A.

CUMBERLAND
Plastics Size-Reduction Machinery

Cumberland "Stair-Step" Dicing Machines



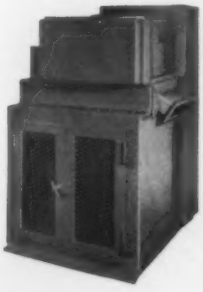
For dicing the *full range* of thermoplastic materials.

Cubes 1/16" to 1/2" produced from plastic sheet or ribbon stock. Pellet sizes altered merely by changing knives. Cubing is done in one severing operation with rotor knives cutting against one bed knife.

All surfaces contacting plastic materials are of corrosion-resistant metals.

Two sizes of machine available to handle sheets up to 7" and 14" in width.

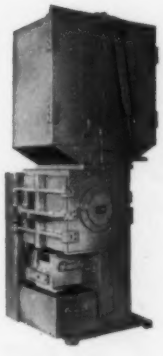
Cumberland Model 20 All Steel Granulator



This heavy-duty all steel machine with 8" by 20" throat opening is suited for granulating tough plastic materials in the form of slabs, bleeder scrap, cylinder purgings, heavy cross-sectional parts, etc.

Frame and cutting chamber are of thick weldments with deep welds. Rotor and seal rings are heat treated and ground all over to provide tough, undamageable parts. Hardened surfaces preserve new appearance.

Machines resist wreckage. All inner surfaces are ground smooth to provide ease of cleaning.



Cumberland Pelletizing Machines

A versatile machine designed for use as a pelletizer, chopper or dicer. As a pelletizing machine: cuts multiple extruded strands of plastic material into cylindrically shaped pieces or cubes for use in molding or extrusion machines. As a notched knife dicing machine: handles principally vinyl sheet stock. A less expensive dicing machine although less universal than the Cumberland "Stair-Step" Dicer. As a chopping machine: efficiently cuts rubber and vinyl slabs into small pieces.

Available in two sizes to handle stock widths up to 14" or 24".

Cumberland Pre-Breaker Granulators

Universal in its application, this dual rotor machine combines a pre-breaking machine and granulating machine in one compact unit. A large throat opening is provided to accommodate bulky reclaim as vacuum formed parts or trim. Also handles extra large and bulky parts and pieces of heavy cross-section as bleeder reclaim slabs, purgings, etc.

A special dome added to top of hopper makes machine ideal for long lengths of extruded pipe, rods, contours and similar items.

Unique hopper prevents any flyback.

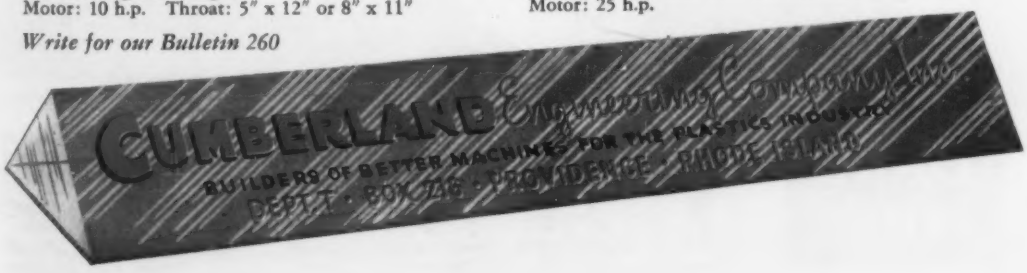
Available in two sizes with 12" x 24" or 24" x 48" throat opening.

GRANULATING MACHINES
For Central Granulating and Use Beside the Injection Press

CUMBERLAND MODEL 0 — V-Belt or Direct Coupled (2 models)
For use beside each injection molding machine. Also for laboratory and miscellaneous uses.
Motor: 1½ or 2 h.p. Throat: 3¾" x 5½"

CUMBERLAND MODEL ½ — V-Belt or Direct Coupled (2 models)
For use beside each injection molding machine. Also for laboratory and miscellaneous uses.
Motor: 3 h.p. Throat: 4" x 8½"

CUMBERLAND MODEL 1½ — Direct Coupled
For central granulating use.
Motor: 10 h.p. Throat: 5" x 12" or 8" x 11"



CUMBERLAND MODEL 10 — V-Belt Drive
For use principally beside the injection press.
Motor: 3 or 5 h.p. Throat: 6" x 10"

CUMBERLAND MODEL 18 — Direct Coupled
For central granulating use.
Motor: 20 h.p. Throat: 5" x 18" or 8" x 18"

CUMBERLAND MODEL 20 — (illustrated above)

CUMBERLAND FINE GRANULATING MACHINE
A machine for granulating to a higher degree of fineness than is possible with conventional machines.
Motor: 25 h.p.

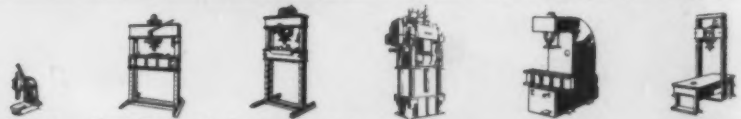
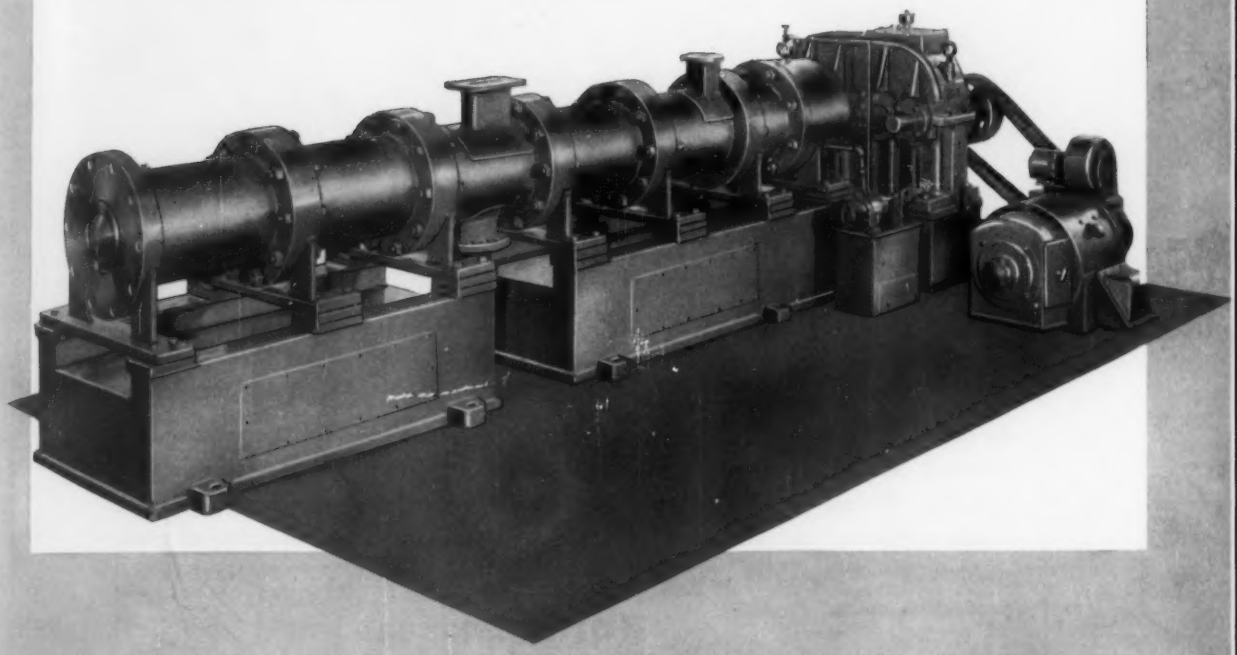
DAKE HYDRAULIC PRESSES



for molding reinforced plastics

Be a pacemaker in the fast-moving plastics industry with equipment designed to keep production geared to modern trends. Dake Hydraulic Presses speed output and reduce costs. They are job-engineered by men experienced in the plastics industry. These men are ready to help you meet special requirements as well as provide better equipment . . . both for compression molding of reinforced plastics as well as trimming and piercing vacuum-formed plastics. Standard models are electric-hydraulic in operation, with capacities ranging from 25 to 300 tons. They are adjustable for stroke, pressure, temperature and timing. Dual palm-operated controls are standard, providing safety in operation. Dake will gladly work with you in developing whatever special press equipment you need.

For descriptive literature on these presses, write for Bulletins 340 and 352.



DAKE CORPORATION 641 Monroe St., Grand Haven, Michigan

DAKE PRESSES

Arbor Presses | Hand-Operated Hydraulic | Power-Operated Hydraulic | Guided Platen | Gap Type Presses | Movable Frame

Specials... THAT'S US

The 8" extruder illustrated fits into a special processing line. Custom designed for a large chemical company, the extruder had to be designed to coordinate with existing processing, blending and mixing facilities.

Extruders for standard operations can be off-the-shelf models but new processes, new products, new ideas require specific designs. For example, in the processing of polyethylene, we developed special extruders for simultaneous hot and cold feeding. In the fields of foamed plastics, polystyrene, polyethylene, the vinyls, we have designed many individual extruders for processing, blending, reclaiming and devolatilizing.

Most new ideas for special equipment originate in shirt-sleeve sessions with a company's production and engineering personnel. They know their process requirements. We translate these specifications into machines tailored to the job.

If you are working on new ideas in either plastics or rubber, H & K can be of assistance. We have specialized knowledge of these fields and can design a complete plant, a special process or an individual machine. We also have complete engineering service.

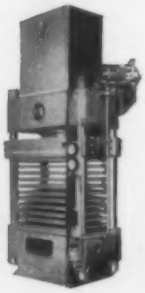
HPMs FOR EVERY MOLDING JOB

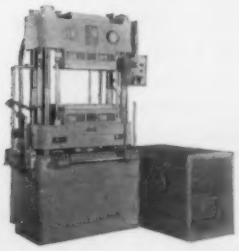
THE MOST COMPREHENSIVE LINE OF PLASTIC MOLDING EQUIPMENT

Choose the method best suited to your needs, then select an H-P-M press to do the job! From the first acceptance of plastics as a highly feasible commercial material, H-P-M has been designing and building molding machines for the plastic industry. Today, H-P-M offers plastics machines for every job—injection, compression, transfer, laminating and reinforced plastics — machines designed to give molders larger capacities . . . faster cycles . . . fewer rejects . . . big savings in production costs.



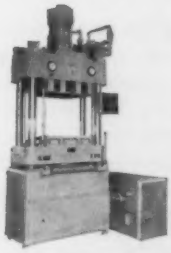
Regardless of your molding application, you'll handle the job better and faster with an H-P-M. Investigate now how an H-P-M will help your production. There's an H-P-M plastics engineer as near as your telephone . . . call him today.

REINFORCED



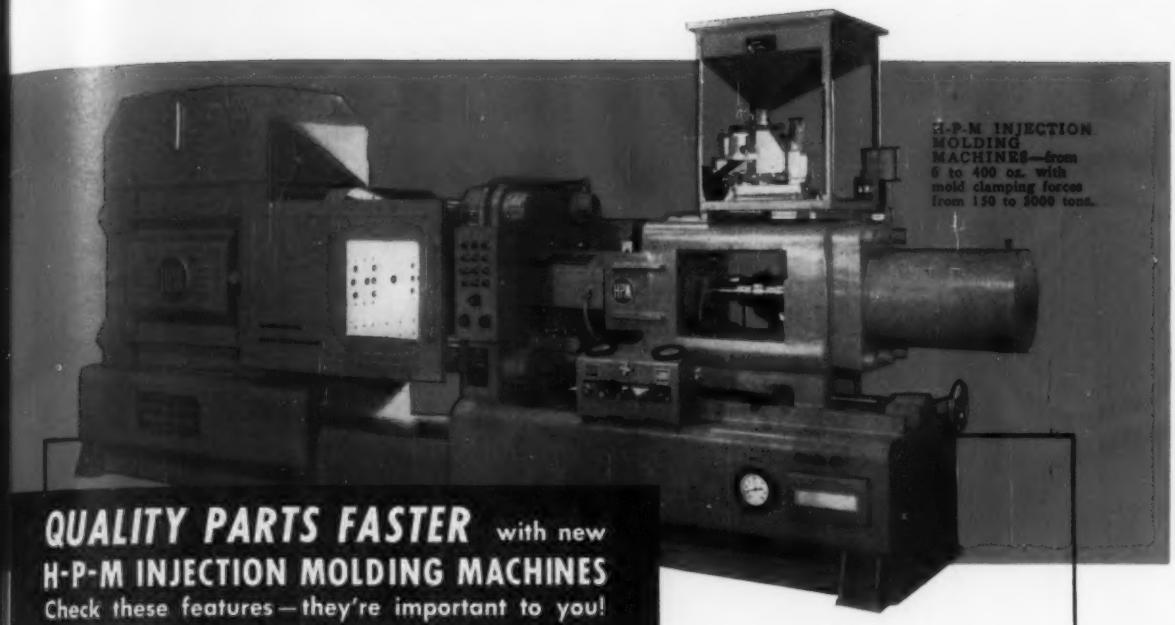
A complete line of stock presses from 50 to 200 tons, designed specifically for molding reinforced plastics. Larger sizes built to order. Write for Bulletin No. 5404!

LAMINATING



Multiple hot plate presses with steam or electrically heated plates for compressing or curing laminated material. Built to customer's requirements.

COMPRESSION



Stock sizes 100, 200, 300 and 500 tons. Larger sizes up to 2500 tons built on special order. Write for Bulletin No. 5702!

TRANSFER

Stock sizes 100, 200, 300 and 500 tons. Larger sizes up to 2500 tons built on special order. Write for Bulletin No. 5702!

H-P-M INJECTION MOLDING MACHINES—from 6 to 400 oz. with mold clamping forces from 150 to 3000 tons.

QUALITY PARTS FASTER with new H-P-M INJECTION MOLDING MACHINES

Check these features—they're important to you!

- **Full Hydraulic Mold Clamp**
- **Large Platens With Plenty of Stroke and Daylight**
- **Over-Capacity Heating Cylinders**
- **Greater Horsepower With Faster Injection Speeds**
- **Manifold Valve System Reduces Hydraulic Piping**
- **Overhead Oil Tank**
- **New Hydraulic System Incorporating Flange Mounted Vickers and Denison Pumps**

MATCHED UNITS PROVIDE CLEARER, ACCURATE GAUGE, EXTRA WIDE FILM WITH MAXIMUM OUTPUT.

Model 350 16 screw diameter MPM Extruder with flat film die

This latest MPM 3½" extruder, incorporating new bearing assembly, with matching flat film die and takeup, is the most advanced and efficient unit of its kind available to the industry. Film can be produced with tolerances as close as .0001" across a sheet .00125" thick. In actual verified production, film up to 58" wide has been produced at the rate of over 200 feet per minute. The unique die design makes it possible, with extra capacity MPM extruders and takeups, to produce sheet up to 100" wide.

More, better, efficient production is the reason why MPM equipment is so widely used.

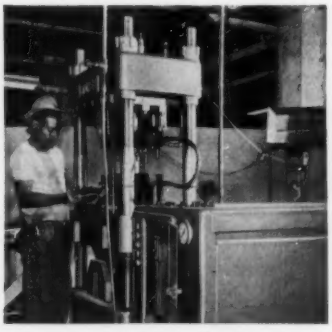
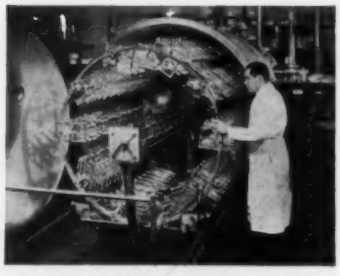
STOKES



Stokes Model 741 fully automatic compression molding presses (125 ton unit shown here) provide highest attainable molding economy plus precision and flexibility. Available in 50, 75, 125 and 200 ton models. Other Stokes automatic presses include Model 800 in 15 and 25 ton capacities, Model 725 in 25 ton capacity and Model 252 closure presses in 50 and 150 ton capacities. Write for detailed catalogs 200, 513, 201 and 521.

A Stokes-Windsor Extruder making rigid PVC pipe at Firestone Plastics Company, Pottstown, Pa. It is also used for blending, compounding and other development of Firestone's Exon resins. Stokes-Windsor Extruders are available in capacities of 65, 120 and 250 pounds per hour nominal capacity. Widely used for making tubes, tapes, sheet, belting, channels, molding and pipe; also for compounding, coloring and pelletizing for molding or re-extrusion. Further details in Catalogs No. 525, 550.



The Stokes Model 701 . . . the 2 ounce *truly* automatic injection molding machine molds, de-gates, ejects and sorts automatically . . . all without operator attention. Positive nozzle shut-off eliminates "drooling", permits full-pressure prepacking of injection cylinder for uniform plasticizing. Standard features include positive ejection, fast 3½ second dry cycle, simplified die set up. Stokes fully automatic injection molding machines are available in 2 to 6 ounce capacities. Write for Bulletin 565.

A modern and greatly improved version of the semi-automatic toggle press which we have been offering for many years. Model 731 is available in capacities of 50 and 150 tons. Ideal for resistor and condenser cores and similar parts. The toggle-type closing gives high initial speed, slow closing, freedom from distortion of inserts. Send for Catalogs No. 526 and 516.

Stokes Preform presses (Model 294 shown above) are available in 4 single-punch and 8 rotary sizes, and one hydraulic. Preforms are made in the range from small button sizes to those as much as 10 pounds in weight. Full details in Catalog No. 509.

This 72-inch Stokes Vacuum Metallizer processes as many as 100 loads per day of toys at Ideal Toy Corp., Hollis, N. Y. Gives brilliant, long-wearing finish in many metallic colors at minimum cost. On metal parts no buffing or polishing is required. Opacity of coating permits use of scrap plastic. Other models of 24-, 36- and 48-inch diameter. Send for detailed and generously illustrated Catalog No. 780.

Two of Stokes Model 727 semi-automatic transfer presses of 200-ton capacity at Kuhn & Jacobs Molding & Tool Company, Trenton, N. J. Top or bottom plunger; capacities 50, 100 and 300 tons. Without the transfer mechanism, this is Model 726, a compression molding press of the same capacities. For more detailed information send for Catalog No. 240.

As a guide to the year's activities on the part of machinery and equipment suppliers in making available new, more improved units for various plastics processing techniques, Recent Developments in each field will be reviewed in this section. All items listed have been excerpted from the New Machinery and Equipment section of MODERN PLASTICS, Oct. 1956 through July 1957 issues. Detailed information can be obtained from these issues.

INSTRUMENTATION

BY ROBERT BANCROFT*

The instrumentation of plastics processing operations has come to mean more than merely the installation of simple measuring instruments to indicate the values of such process variables as time, temperature, pressure, viscosity, and others. It includes control devices, frequently coupled with such instruments, to sense process deviations from preset control points and to make the necessary adjustments in the process to maintain operating conditions at established levels.

By holding process variables within closer limits than is possible by manual control and at far less cost, process control equipment is playing an ever-increasingly more important role in insuring optimum functioning of plastics fabricating equipment.

Compression molding

Three separate control systems are involved in compression molding of plastics: 1) control of the hydraulic system which actuates the prime mover; 2) temperature control of the platen to which the mold sections are attached; and 3) regulation of an auxiliary air supply.

The hydraulic power supply for the press normally consists of a high-pressure pump feeding a surge tank which acts as the high-pressure source for the press. The pump is usually left running continuously, and a pressure-loaded, self-operating-type pressure regulator, installed on a pump by-pass, is employed to maintain the desired constant pressure in the high-pressure system. An electrical overload limit switch, on the power supply to the pump motor drive, and a spring-loaded, high-pressure safety relief valve on the surge tank are control devices for protection of the equipment. Cycle timers controlling solenoid valves in the hydraulic system provide for automatic operation of the sequential steps in the molding process.

The mold temperature may be

* Senior plastics engineer, Minneapolis-Honeywell Regulator Co., 2753 Fourth Ave., S., Minneapolis, Minn.

Recent Developments were prepared by the editors.

ntrolled in various ways, depending upon the type of heating system selected. Where electrical resistance heaters are used to heat the platen and/or mold, a simple bi-metal thermostat is often used for on-off control. When the platens and/or mold are cored, condensing steam may be employed as the heating media with a simple spring-loaded pressure regulator to control the steam temperature. In cases involving hot or cold water systems, a self-acting control valve with a vapor or liquid expansion bulb immersed in the water line frequently provides the desired control action.

The auxiliary air supply needed for cleaning the mold cavity of flash, lubricant spraying, ejection of molded parts, etc., at the end of each cycle is usually drawn from a central "house" system. In general, this system is comprised of an air compressor directly connected to a surge tank which acts as a reservoir to feed the system. A dual pressure limit switch usually serves to control the pressure in the surge tank through on-off control of the electric power supply to the compressor. Simple spring-loaded, self-operating pressure regulators are used at each station in the house system to supply air at the desired pressure; a spring-loaded pressure relief safety valve is also installed on the surge tank for protection of the system.

Transfer molding

The control equipment used in conjunction with transfer molding is very similar, in most respects, to that employed in compression molding. Additional control equipment is needed to handle a second complete hydraulic system[1], preheating of preformed mold charges, and other ramifications arising in processing different types of materials.

In transfer molding operations, one hydraulic system serves to close the press and hold the mold in a clamped position while a second hydraulic system is commonly used to provide the force for driving the transfer ram.[1] Although the individual control devices used are much the same as those in the hydraulic systems for compression molding, a bit more complicated arrangement of pressure regulators and valving is necessitated to provide the system with the flexibility desired in volumetric capacity and pressure. To rapidly close the press, high volumetric capacity at low pressure is used. As the press nears the closed position, a cam-actuated limit switch energizes a multiport solenoid valve which switches from the regulated low-pressure piping circuit to one at high pressure and low capacity to complete the clamping of the mold. Similarly, in driving the transfer ram, a high volumetric capacity at low pressure is initially desired with the ability to switch to a low capacity, high pressure, as the completion of the transfer is neared. An accumulator tank with a pressure-regulated pneumatic inner bladder is commonly used to augment the pump capacity at low pressure; for high-pressure delivery, the pump is directly connected to the press cylinder. A spring-loaded, self-operating pressure regulator on the house air line serves to

[1] Except for the older three platen presses with floating transfer pots, two or more controlled hydraulic systems are required for transfer molding operations.

RECENT DEVELOPMENTS

The Jordan Dancetrol provides automatic tension control from a few ounces up to several hundred pounds in the winding of paper, plastic webs, and tapes. It holds constant web velocity up to several hundred ft./min., is readily adapted to dancer rolls or pivot arms on existing machines, and may easily be incorporated as part of a new machine. *The Jordan Co., 3235 W. Hampton Ave., Milwaukee 9, Wis.*

A new instrument for controlling quality of film is the Viking hole detector. The standard model tests nonconducting materials up to 25 mils thick and detects holes 15 mils in diameter and larger at speeds up to 1500 ft./minute. With a 2- or 3-position recorder, the holes are not only recorded and counted, but located. *Viking Instruments, Inc., East Haddam, Conn.*

The E364 Robotron Control is a completely packaged unit that will automatically close a hydraulic press, freeze the mold at the right time, relieve gases by "bumping" at intervals, etc. Some advantages are: cycles may be reset in a few seconds, the operating pushbuttons are located on the case, and the solenoid-operated air valve is within the case. All relays are of the plug-in type for easy checking and servicing, and are completely enclosed for safety. *Emmett Machine and Mfg. Inc., 445 E. Turkeyfoot Lake Rd., Akron 19, Ohio.*

A new producer has entered the beta-ray gage field with a line of five Atom-At gages: a transmission gage for paper, foils, plastic films, etc.; a backscatter gage for coatings accessible from one side only; a differential gage for coated films; a multi-head gage for wide webs of coated films; and a transverse profile portable gage that measures thickness across the whole width of a sheet. *Nuclear Corp. of America, Inc., Empire State Building, New York 1, N. Y.*

Designed for use in printing, coating, tubing and rerolling, slitting and punching, tentering, intersheeting, and manifolding, the Linear Edgetrol photoelectric edge guidance system controls edge registration and web position of opaque materials, porous materials (lace, gauze, netting, nonwoven fabrics), single thickness film (polyethylene, vinyl, cellophane), and laminates. Edgetrol systems are available in three integrated forms for use with present web control equipment as well as in new types of applications. *Intercontinental Dynamics Corp., 170 Coolidge Ave., Englewood, N.J.*

maintain the back pressure in the accumulator tank. Electrical cycle timers working through relay circuits control multiport solenoid valves in each hydraulic system to carry out the press cycle of operations automatically.

Preheating of preformed mold charges is commonly accomplished in dielectric preheaters at each press with cycle timers acting to control the power supply to each preheat furnace.

Molding jobs requiring more critical control of temperatures and/or pressures during the molding operation are handled by proportional-type controllers, often also including a continuous record chart of the controlled variable plotted against time.[2] The control means or actuator may be either a pneumatic or electric motor-driven valve on a condensing steam or controlled water system supply line. Where electrical heating is involved, the motor drive operates a slide-wire rheostat to control the electric power input. In either case, cycle timers are usually used.

Injection molding

Injection molding, like transfer molding, commonly requires two or more controlled hydraulic systems plus auxiliary control systems for metering the charge, preheating the charge prior to injection, maintaining the mold sections at optimum temperatures, providing a regulated house air supply, and for controlling various special ramifications of the process such as automatic lubrication.[3]

In injection molding processes, a relatively low-pressure hydraulic system serves to close and clamp the mold while a high-pressure system is employed for driving the injection ram. As in compression molding, it is desirable for both hydraulic systems to provide flexibility in delivery pressure and volumetric capacity. The types of control equipment used in the hydraulic systems for injection molding and transfer molding are essentially the same.

The charge stock fed to the heating section of the press is metered either volumetrically or gravimetrically. Where volumetric metering is used, a cam mounted on the injector ram drives a variable stroke metering plunger. In gravimetric metering, the cam actuates a limit switch which triggers a dump solenoid when the molding machine is ready to receive the charge from a weigh bucket. An electrical time delay relay controls the interval during which the dump solenoid stays energized at the beginning of the injector ram stroke.

Encasing the cylinder of the injector ram is a multiple-zone preheater designed to melt and heat the charge to the optimum temperature and/or viscosity condition for injection molding. In common practice, separate electrical resistance heaters supply the heat for each zone with variations of on-off control through thermocouple-actuated millivoltmeter limit controls or pyrometers functioning on the principle of timed proportioning of electrical pulses.

Separate cooling systems are commonly used for maintaining optimum temperatures in each section of the mold.

A typical installation would consist of a centrifugal circulating pump drawing coolant from a controlled temperature reservoir or sump and feeding it to the manifold supplying the mold. The flow is controlled by vapor expansion bulb, mercury switch-type thermostats actuating solenoid valves on the supply manifold. The temperature of the coolant in the sump tank is regulated by additional vapor bulb-mercury switch thermostats controlling on-off, immersion-type, electrical resistance heater elements in the sump or actuating solenoid valves on cold water coils in the sump. A spring-loaded back pressure regulator mounted in the pump discharge manifold serves to maintain a constant supply pressure to the mold. An electrical overload switch is used to protect the pump motor drive.

A controlled house air supply is needed to supply compressed air for dislodging parts stuck in molds, cleaning molds of flash, etc. This control system was outlined above in the discussion of instrumentation for compression molding.

Special control systems have been devised to meet particular needs of various sorts. An interesting example is a cycle timer-controlled, automatic lubricating device[3] that provides a preset amount of lubricant directed at given portions of the mold after every set number of operational cycles. Cycle timers, working through relay circuits, actuate solenoid valves to achieve this function.

Extrusion

The extrusion process consists of two major steps: 1) the extrusion operation proper and 2) final processing of the extruded product. Variables to be considered in controlling the first step are: a) the operating speed of the screw; b) thermal gradient along the cylinder; c) back pressure in the screw cylinder, and d) feed temperature at the die head. Control of the final processing depends upon the nature of the extruded product. With so many diverse forms of extruded products, no attempt is being made in this general discussion to cover the many special control problems involved.

Optimum control of the extrusion operation presents some knotty problems. The inherent nature of the charge stock serves to confine many parameters, of course. The design of the screw, a subject of much controversy, further defines the operating parameters.

The charge is preheated to the desired state for extrusion by frictional heat as well as externally applied heat. While much of the heating is due to mechanical friction, it is probably most common to set a fixed rate of speed for the screw for each individual extrusion operation, and control the temperature gradient of the charge through external cooling or heating, as the need may be. Control of the screw speed is commonly accomplished by means of a mechanical variable-speed drive attached to a gear-head motor. The motor is pro-

[2] "Molding Plastic Tips," C. H. Miller, *Instrumentation*, Volume 7, Number 4, 3rd Quarter 1954, pp. 17-19.
[3] The device described was designed and put into use by methods engineers in Minneapolis-Honeywell's Plastic Molding Department.

tected against overload by an overload limit switch on the power supply line.

The large changes of viscosity and frictional characteristics with temperature, inherent in thermoplastics, necessitate close temperature control for extrusion operations. Accordingly extrusion machines are usually designed with multiple-zone cylinder heaters, the screw chamber walls being cored and/or jacketed. Electrical heaters are commonly used to supply heat while water or air serve as cooling media. Thermocouple-actuated multivoltmeter limit controls or proportioned pulse-type pyrometers, as previously mentioned in the discussion of controls used in injection molding, are commonly used for an on-off control of the electric power supply and to actuate solenoid valves on water or air cooling lines. While heat is normally supplied in the initial preheat zones to melt the charge, in many cases it is necessary to remove excess heat generated by friction in some zones, particularly if the machine is being operated at a high output rate. Similar controls maintain the feed temperature at the die head. Back pressure in the screw cylinder is determined by the design of the breaker plate and screens mounted at the discharge end of the chamber.

Summary

Control equipment is being employed in ever-increasing amounts to insure optimum results from plastics fabricating processes. At the present stage of development, the majority of the operations are but semi-automatic at best. With relatively broad tolerances allowed for many of the controlled process variables, comparatively simple control equipment is capable of providing the degree of control required. A number of ingenious control circuits have been contrived using these simple control elements to carry out sequential timed control functions very satisfactorily. Where more critical control of such key variables as temperature and pressure are involved, the more sensitive proportional-type controllers have been advantageously employed, often including recording of controlled variables.

EQUIPMENT FOR INJECTION MOLDING

BY ROLF PELIKAN*

An injection molding machine basically consists of the following component parts:

1) A steel frame or structure on which all parts of the machine are mounted, as listed below.

2) A hydraulic system consisting of motor-driven pumps, in which a hydraulic fluid, usually oil, is subjected to high pressure. This fluid, controlled by directional, pressure-reducing, unloading, and pilot valves, makes movement of parts possible.

3) Two hydraulic cylinders, complete with pistons and rods or rams. One is called the injection cylinder, the other the clamping cylinder. The pistons and rams of both these cylinders are advanced and retracted by the fluid pressure generated.

4) A heating cylinder, in which cold feed pellets are heated until they melt. The injection ram forces cold material into the heating cylinder which in turn forces the previously plasticated melt through the orifice into the mold.

5) Two thick steel plates, called mold or die platens, to which the two halves of the injection mold are clamped. One of these, the stationary platen, carries the so-called cavity half of the mold. To the other, called the movable die-platen, is clamped the core or ejector half of the mold. Both platens are mounted on closely aligned tie-bars, or on ways which are machined to close tolerance. The movable platen is set in motion by the clamping ram, either connected to it directly or by means of a system of links and toggles. Opening and closing is done by either retracting or advancing the clamp ram.

6) An electric system, consisting of limit switches, timers, and solenoids is needed to control time and sequence of the various operations of the machine. Electric heating elements, controlled by the "off and on" type pyrometers or the more accurate proportioning-type pyrometers, furnish the necessary heat for the proper functioning of the heating cylinder.

In addition to these basic component parts, various pieces of auxiliary equipment are needed to give the molder necessary flexibility and to enable him to cut costs by: a) reducing cycle time, b) eliminating or decreasing high cost of direct or indirect labor, and c) saving of material consumption. Time, labor, and material are the three main factors that make up total cost. Auxiliary equipment, used in conjunction with new molding techniques and continuous refinements in the design of modern molding machines have contributed greatly to lowered manufacturing cost. This is of the utmost importance to the molder in this highly competitive market.

Devices, techniques, and machine improvements can therefore be categorized with a view as to which of the three main cost factors they influence and reduce.

Time-saving devices

With operating costs at an all-time high, time-saving devices are always regarded with the greatest interest. Builders of molding machines have recognized this fact and have tried to improve performance and reduce cycle time of their machines. Faster ram speeds, in clamping as well as injection cylinders, have greatly contributed to increased output in shorter time.

Cycle time can also be cut by shortening and adjusting the ram travel on the die opening stroke, not only on the so-called all-hydraulic models but also on the link-type machines. Prepositioning of the injection ram (plunger advance) enables the molder to save valuable seconds on every injection stroke. Plunger advance can now be found on practically every modern injection machine. Many molding machines now also carry a "material prepacking de-

*Equipment Engineer, Ideal Toy Co., 184-10 Jamaica Ave., Hollis 7, N. Y.

Recent Developments were excerpted by the editors from MODERN PLASTICS, Oct. 1956 through July 1957.

Several Formatons have been added to a line of injection molding machines. (Formatons are machines using a vertical clamp to allow the molded products to drop off ejector pins or stripper rings; removal of product is accomplished with an air blast which carries the parts out of the mold and into a chute that has been attached to the rear of the machine.) Formaton-2 Model A has a capacity of 2 oz./shot. Formaton-3 Model A is a 3-oz. version of the Formaton-2. The Formaton-C combination automatic injection machine incorporates features of the Formaton-A 3-oz. and -F 4-oz. machines. *Guy P. Harvey & Son Corp., Leominster, Mass.*

The Lester "package maker" is now being offered in four different filling speeds. The L-2-4-oz. standard model can fill at the rate of 7.8 cu.in./sec. at a shot pressure of 20,000 p.s.i. *Lester-Phoenix, Inc., Cleveland, Ohio.*

A new maker enters the injection machine field with a line of machines in the middle-capacity range. Models 400 and 800 feature a closed-circuit hydraulic system and a reversing Oilgear pump that eliminates hydraulic shock. They are equipped with a metering-type vibratory feeder, but will be furnished with Exact Weight scales if desired. Plug-in-type controls are grouped at eye level. *National Automatic Tool Co., Richmond, Ind.*

The Battenfeld line of injection machines (built in Germany) consists of 17 models ranging in shot capacity from ¼ to 52 ounces. Some of these machines are horizontal, some vertical, and up through the 16-oz. size either type can be had. Top injection pressure is 28,400 p.s.i. in all sizes above 5 oz., lower in the smaller models. *Molding Systems, Inc., Danielson, Conn.*

The Asmidar APM 21 is a hand-operated injection machine that is capable of molding all thermoplastics and is well-suited to making small numbers of test shots. Top injection pressure is 5700 p.s.i. *British Machine and Foundry Supplies, Ltd., 80 Shore Rd., Port Washington, N. Y.*

Thermastrip heating bands are said to be 40% more efficient than any other type. They consist of Calrod-type heating elements encased in aluminum, and feature full-circle heating, uniform heat distribution, and low loss to the surroundings. They are available in 1.5- and 2.5-in. widths, and in diameters from 4 to 12 inches. Larger bands can be made to order. *Thermal, Inc., 9400 Robinson Rd., Franklin Park, Ill.*

Featuring a radically different preplasticator mechanism, the Lewis Model 616-PP-12 is the first production machine used to mold the low-pressure linear-type polyethylenes. The new preplasticator, which was designed particularly for this 8-oz. machine, raises its shot capacity to 22 ounces. It has a nozzle shut-off valve that does away with the need for holding pressure on the ram after injection (unless the mold is to be packed). *Lewis Welding and Eng. Corp., 2300 St. Clair Ave., Cleveland 17, Ohio.*

Small injection press models 357 and 357A have been furnished with an auxiliary 5-g.p.m. pump that cuts their dry-cycle time to just over half that of the earlier models. The two machines are rated for 2.75 oz. of polystyrene per shot at pressures of 20,000 and 10,000 p.s.i. with dry-cycle times of 3.3 and 4.6 sec. respectively. *Clifton Hydraulic Press Co., 289 Allwood Rd., Clifton, N. J.*

The model 300 TL injection molding machine is a horizontal machine with a rated shot capacity of 12 oz. of polystyrene, with up to 16 oz. with prepacking. *Reed-Prentice Corp., Worcester 4, Mass.*

The Impco HAS-275 is an 8- to 10-oz. machine specifically designed for automatic molding of deep-draw parts requiring a long stroke. The stroke, adjustable to 14.2 in., can be reset without upsetting adjustments. *Improved Machinery Co., Nashua, N. H.*

In-line preplasticator for the Peco 30M injection machine which shoots up to 8 oz. of polystyrene, embodies a new principle of preplasticator design The preplasticator is coaxial with the heating cylinder, the nozzle of which acts as the plunger for the preplasticator. Injection pressures on the hot melt up to 9800 p.s.i. can be obtained. *Peco Machinery Sales, Ltd., 28 Victoria St., London, S.W.1, England.*

---

vice," which is a modified plunger advance system. This device enables the molder to pack more feed material into the heating cylinder by repeated advancing and retracting of the injection ram. The advance of the ram is controlled either by an electric timer or a limit switch, allowing the plunger to go just far enough to introduce more material into the cylinder without exerting so much pressure as to force material into the mold. Thus more material can be plasticated per cycle, enabling the molder to run larger than standard shots on his machine, and so uprate his machine capacity.

Most manufacturers of molding machines and equipment have recognized the fact that a machine will not be able to perform faster or better than the efficiency of the heating cylinder will permit. Advertised dry-cycle-time and actual operating performance under load are often quite different and it is found that the actual speed of operation and performance is to a great extent controlled by the efficiency of the heating cylinder, i.e., its capacity

to plasticate material fast enough to keep up with the modern fast-running injection, clamping, and ejection devices.

Many improved heating cylinder designs have been put on the market. Conventional, spreader-type cylinders are now designed with longer bodies, higher wattages are provided, and the internal design of the cylinders has been so changed that higher rates of heat transfers are obtained, thus speeding up the plasticating process.

Another great step forward in raising the capacity of the heating cylinder has been in the application of preplasticators. As the name implies, material is plasticated before it is needed. It is then conveyed to the injection cylinder by means of an extruder-type screw mechanism or by a reciprocating auxiliary plunger. It is obvious that in this method there is always enough melted material ready to be injected, as the preplasticating chamber is constantly being refilled throughout the cycle of the machine. Usually, the one retarding factor in this process results from the fact that most molded articles need a certain cooling time in the closed mold in order to solidify the material properly. Close attention has to be given to the design of molds scheduled to run in preplasticators, especially to the layout of water channels, so that maximum cooling can take place in the shortest possible time.

Besides these conventional heating cylinder models, a new type of cylinder, the "melt extraction" type, has been introduced. This cylinder has a perforated inner liner, in contact with the outer cylinder wall where the heat transfer takes place. As the material softens it is forced through the perforations of the inner liner and is channeled to and ejected through the nozzle into the mold. It is claimed that the melt extraction type cylinder gives more uniform melt temperatures and that it speeds up the plasticating process. Their design is complex, however, and they seem to serve best when they are designed for molding a particular plastic.

Special attention has been given in recent years to maintenance and mold setup problems, in order to keep "down-time" to a minimum.

Hydraulic manifolds are now widely used to provide compact, easily accessible hydraulic systems with most hydraulic valves in one central location. The use of manifolds, flexible hydraulic high-pressure hose, and lately, high-pressure swivel pipe fittings has eliminated many leaks which were due to vibration of rigid piping or caused by strains in piping due to faulty assembly. Flexible, high-pressure hose has in many instances replaced the hard-to-handle seamless steel tubing used in the past. The new, flexible hose assures leak-free operation and quick replacement in case of damage.

A feature which has helped greatly to cut down mold setup time is the auxiliary hydraulic cylinder used for quick, effortless nozzle setting. Old-style ratchet-type systems are being replaced by motor-driven gear systems, which facilitate the clamping setup of the link-type machine. The need for greater accessibility to mold clamp areas has been recognized and machine frames have been so laid out that molds can now be clamped with greater speed.

Another important time-saving factor is now in the making. The Injection Machine Division of the S.P.I. has set forth standards for the layout of knockout pins, platen bolt-hole patterns, and nozzle lineup rings which will make a great degree of interchangeability possible. The molder will be able, in the future, to switch molds from one machine model to the other without the added expense of making tool alterations. This is a very important step, as considerable time and money has often been spent in adapting a mold, designed to run in one type machine only, to fit another. This will be particularly welcome news to those molders who plan to have machines of different manufacture in their shops.

Material-saving devices

An important development in material savings in recent years has been the perfection of a new molding technique, based on a new mold design. This new design has brought about the process called "hot-runner molding." In this process, the material of sprues and runners is kept in plasticated state by means of heating elements which are controlled by sensitive instruments. This material is injected into the cavities through all-enclosed runner systems. The advantage of this technique is that less material is removed from the mold per cycle, since only the molded piece with its small center gate is removed, and sprues and runners remain in the mold. Scrap of runners and sprues is completely eliminated and degating has been greatly facilitated. In addition, it is reported that center gating, which in hot-runner molding is the conventional and accepted way of introducing material into the cavity, has greatly cut down reject figures due to shorts, strain, and flow marks. Another important advantage in the use of the hot-runner mold system is the fact that the melt temperature can be kept lower, in the safe range, thus avoiding brittleness and other defects in the finished article.

Weigh-feeders also save material, and even more important, they improve control of quality. A weigh-feeder is a sensitive balance which automatically weighs each charge of material before it enters into the cylinder. Automatic or manually operated compensating devices correct any variance of weight of the material fed, insuring trouble-free operation. Wall cross-sections of molded parts can be kept much more uniform throughout the production run of the mold, overpacking of molds is eliminated, and considerable material savings can be achieved. Recognizing this advantage, many machine manufacturers offer weigh-feeders as standard equipment with their machines.

Another method of flash prevention is a rather simple system of accurate microswitches so set that they will break an electric circuit as soon as the faces of the mold have separated a few thousandths of an inch, due to the pressure exerted by the in-

jected material. The breaking of that circuit de-energizes a solenoid-operated hydraulic valve which switches the injection stroke automatically to low pressure, thus preventing flashing of the mold.

Labor-saving devices

Devices designed to eliminate or decrease the high cost of direct or indirect labor, where this can be done safely, have been viewed with particular interest by the injection molder. Of these, automatic molding devices are the most widely used. Known for several years in the industry, these low-pressure-closing, recycle, automatic-ejection, and alarm systems have been improved and modified and are now standard equipment on many new molding machine models, especially from the 12-oz. class down.

The special feature of the low-pressure-closing system is the fact that full clamping force is applied only when the faces of the mold have met. The mold is closed under low pressure to prevent damage to cores and cavities in the event that a molded piece has not been ejected properly and is stuck in the face of the die.

Special emphasis has been put on the problem of shot removal from the mold. The original automatic molding systems were provided with air valves, either mechanically or electrically operated, which directed a combination of air streams into the mold at the moment of full ejection. These air streams blew the molded articles off the cores and ejector pins and directed the shot downward into a bin or pan located under the tiebars of the machine.

In recent years, new shot-removal systems have been developed in which shots are removed from the mold by sweeping devices or combs activated pneumatically or hydraulically. These systems give more positive assurance of complete shot removal than does an air blast. Combs or sweeping devices are so designed that they cover every part of the mold face and ejection system. It is often difficult to direct air streams so that they do not interfere with each other or cancel each other out and so neglect areas of the mold. It is of course necessary to protect molds and combs with a system of interlocking micro- or limit- switches which will prevent the mold from closing before the sweeping device has cleared the mold faces.

Another important labor-saving device is the small scrap grinder, set up next to the molding machine and run by the machine operator. This unit will regrind sprues, runners, and rejects on the spot, thus eliminating the need for expensive material handling and redrying. In the design of new models special emphasis was placed on rigid construction and easy accessibility to cutting knives for repair and cleaning purposes, so that down-time could be held to a minimum, and color and material changes could be made quickly.

A great deal of labor is expended on loading feed, as all raw material must be fed into the machine through a material hopper which is at a considerable distance from the floor. Much work has been done in developing automatic devices to raise material to the hopper. These automatic material loaders use compressed air on the Venturi principle, or work by means of small fans. In earlier models great difficulty was encountered in lifting reground materials or so-called fines. Clogging of tubes usually resulted. In the last couple of years improvements were made and design changes incorporated with the result that there are now several models of material lifters on the market which can be used universally on all materials. Another development in conjunction with equipment of this kind is the use of a combination regrinder and hopper loader which combines the features of the abovementioned devices and so reduces handling and transportation cost.

The most obvious over-all trend in the industry seems to be toward specialized equipment to meet the specific needs of molders. Machines with extra-long die-opening strokes for so-called deep draws, especially desired by the housewares molder, molding machines with vertical mold openings for the insert molder, and special nozzles with heat control devices and combination dehumidifier-preheaters for the nylon molder are but a few examples of specialized equipment now in use.

EQUIPMENT FOR COMPRESSION AND TRANSFER MOLDING

A compression press consists essentially of a ram in a cylinder or pot, the pot being tied to a resisting head member through strain or tie rods. A movable platen equipped with bushings, one for each strain rod, is mounted on the outside end of the ram. Thus, clamping action occurs between the top of this movable platen and the flat underside of the press head. The ram is usually hydraulically operated. There are a few mechanical toggle presses too, and a combination hydraulic-pneumatic press. Hydraulic power is delivered either by a central accumulator system or by separate pumps that can be adapted for each press.

Although many presses today are self-contained—that is, are equipped with all controls as well as their own pumps—there are many plants which operate with a central pressure system which supplies hydraulic power for the entire plant. These central systems require high-pressure pumps, low-pressure pumps, and also hydraulic pressure accumulators.

Three types of accumulators are in standard use. In one, the accumulator piston raises a heavy weight against gravity, and the weight is adjusted to give the desired hydraulic pressure. In another, the accumulator piston acts against a compressed air piston of much larger diameter, and the force exerted by the air produces the hydraulic pressure. In the third type, the water is pumped

Recent Developments were excerpted by the editors from Modern Plastics, Oct. 1956 through July 1957.

against a volume of compressed air; the compressed air is located in a tank.

The different types of compression presses are designated according to their method of control, that is, 1) hand-operated, 2) semi-automatic, and 3) fully automatic.

The designation hand-operated indicates that the motions of the press are actuated by manually controlled valves. Such a press may be used with what is known as a hand mold, so called because it is not permanently mounted in the press, but is removed from the press after the curing cycle has been completed, and dismantled on a convenient bench placed near the press.

After the part has been removed from the mold, molding compound and inserts, if required, are placed in the cavity of the mold, the force plug is placed in position in the mold, and the entire assembly is manually positioned on the lower platen.

The hand-operated press may also be used with the two halves of the mold permanently assembled on the platens of the press. In this case the mold may be equipped with knockout pins which are actuated by the motion of the press; or the mold may be of a simple design requiring only a blast of air to remove the part.

In a semi-automatic press, the mold is generally mounted permanently in the press, and the only difference between the operation of this type mold in a hand press and in a semi-automatic press is that in the latter case the operator starts the molding cycle by pressing a button or other control, and the complete cycle of mold closing, curing, and mold opening proceeds without further operator attention. The cycle, however, comes to a dead stop after the mold is open, and it is necessary for the operator to recycle the machine manually after the molding material has been loaded in the mold. All types of auxiliary equipment, such as knockout pins, side angle draw bars, etc., can be included in this semi-automatic cycle arrangement.

In the case of the fully automatic press, no operator attention is required. All functions of molding, from material loading right on down to the ejection of the part, are completely automatic.

Any one of these types of presses can be further considered as upward-acting, downward-acting, and angle presses. In the case of the upward-acting press, the hydraulic ram moves upward and the hydraulic cylinder or pot is mounted in the base of the press. In the second or downward-acting type, the pot is mounted on the head of the press,

RECENT DEVELOPMENTS

The Stokes Model 741 line of presses has been completely redesigned for greater speed, dependability, and safety. Available in ratings of 50, 75, 125, and 200 tons, the new presses are fast closing and fast pressing—closing times are only 2.9 sec. from feed to mold contact, while pressing speed is adjustable up to 27 in. per minute. The platen areas range from 28 by 16 to 38 by 22 in. *F. J. Stokes Corp., 5500 Tabor Rd., Philadelphia 20, Pa.*

The Models 150-22 and -33, with 75 tons capacity, are especially engineered for precise control of temperature and pressure. Platens are 14 by 14 in., the Model 22 having two, the 33 having three. Total daylight opening is 6 in., stroke is 6 in., ram diameter is 6.5 in. Closing speed is 50 in./min., and the ram returns (falls) under its own weight when pressure is released. Available temperature range is 150 to 550° F. with built-in electrical heating. *Atlas Hydraulics, Inc., 3576 Ruth St., Philadelphia 34, Pa.*

Designed to provide a wide range of experimental pressing conditions, a new PHI 300-ton press offers three high-pressure ranges: 0 to 10 tons, 0 to 60 tons, and 0 to 300 tons. Each range is provided with its own gage, so that any ram force from 1000 to 600,000 lb. can be maintained with high accuracy. Two built-in, dual-scale pyrometers indicate the temperatures of the heated platens. *Pasadena Hydraulics, Inc., 273 North Hill Ave., Pasadena, Calif.*

The Elmes 300-ton hydraulic compression press is especially designed for convenient use in pairs, two presses being run by a single operator. Available in right- and left-hand models, the press has a stroke of 18 in. and an operating pressure of 2640 p.s.i. The opening between platens is 44 in., and dies up to 36 by 30 in. can be accommodated. Operating speeds in in./min. are: advancing, 309; pressing, 15; and returning, 131. *American Steel Foundries, Elmes Engineering Div., 1150-B4 Tennessee Ave., Cincinnati 29, Ohio.*

The Model 400-150 press, said to be the first automatic 150-ton press, automatically performs such operations as feeding, degassing, ejection, and flash clean-out. It also features a wide range of closing speeds—from 6.1 to 355 in./minute. The loader makes it possible to feed as many as 40 cavities per cycle; several tubes may be directed to feed into a single cavity, or may be shut off completely, as desired. The number of cavities fed can be changed in a few minutes, so very little extra setup time is needed to adjust the feeder when molds are changed. The stroke of the press is 15 in., and its daylight opening is 30 inches. *Baker Brothers, Inc., P.O. Box 101-Station F, Toledo 10, Ohio.*

The Model 99-A fully automatic transfer molding press is particularly well-suited for getting into production quickly and at low cost, on low-quantity runs, and for economical molding of small parts. Air-operated, the press requires a ⅛- to ¾-hp. air supply at 80 p.s.i. Transfer pressure adjusts to 9000 p.s.i., while the clamping capacity is 15 tons. *Hull-Standard Corp., Abington, Pa.*

and the movable ram goes downward to clamp. The angle press is somewhat different in that it consists of either an upward- or downward-acting mold clamp, tied to a horizontal-acting hydraulic ram and cylinder assembly. This special type of press is used for certain molding jobs which require mold opening in more than one direction.

Press capacity

Certain specifications for compression presses are more important than others; for example, most compression presses are rated as having a capacity of "X" tons. For example, a 150-ton press will have a clamping pressure of 150 tons between its movable platen and the head of the press when operated at the specified hydraulic pressure. Because of the factor of safety which is designed into the various elements of most hydraulic presses, this pressure can be raised somewhat, thus increasing the tonnage. In the majority of cases, however, accumulator-operated presses are designed to operate at hydraulic pressures of 2000 to 2200 p.s.i. In the case of self-contained presses, the hydraulic pressure is controlled by the pumping equipment installed by the manufacturer. Presses are available in capacities from 5 to 3000 tons.

The platen area of a compression press indicates the maximum size mold which can be mounted in the press. In some cases, of course, molds somewhat longer or wider than the platen area can be operated in a press with a portion of the mold projecting outside of the platen area; however, this is not recommended. Because of the very high pressures used, the portions of the mold projecting outside of the platen might tend to bend slightly, causing excessive flash and poor cut-off.

The "daylight" opening refers to the maximum possible space obtainable between the inside of the head of the press and the movable platen.

Transfer molding and presses

A compression press can be simply converted to transfer molding. In this case, a second movable platen or bolster plate is mounted between the ram platen and the head. A transfer pot or chamber is mounted on the top of this movable bolster plate, and a fixed ram, the outside diameter of which is slightly smaller than the inside diameter of the pot, is mounted under the head of the press directly above the pot. A sprue bushing, which serves to deliver the material from the transfer pot to the mold, is designed so that it will go through the bolster plate and screw into the bottom of the transfer pot.

In this type of transfer molding, the mold clamp available depends upon the diameter of the transfer pot, since the only force available for both mold clamp and transferring is derived from the single hydraulic ram of the press.

A transfer press is essentially a compression press equipped with an additional or auxiliary hydraulic ram. The clamping ram of the press may be either upward- or downward-acting, with the transfer ram operating in a direction opposed to it. An angle press may be used for transfer molding, in which case the molding material may be transferred into the mold either by the vertical-acting ram or the horizontal-acting ram; the second ram acts to open, close, and clamp the mold.

The use of a two-ram or transfer press for this type of molding permits the use of more cavities in a mold than it is possible to use in a single-ram compression press converted to transfer molding. This condition is made possible since the total available clamping capacity of the press is entirely used for clamping, whereas in the case of the single-ram transfer method, a sizable portion of the clamp ram's tonnage is used for transfer pressure, and is thus lost to the clamp section. Although the two-ram-type press is used with the transfer setup, making use of a separate transfer pot, it is generally used with what is known as pressure-type transfer molds. This type of mold has the transfer pot built directly into one half of the mold. The diameter of this pot is slightly larger than the diameter of the transfer ram.

With the transfer ram in the withdrawn position, preforms of molding compounds are dropped into this hole, and the action of the transfer plunger causes the material to flow through the runners and gates into the cavities of the mold. With this design, no sprue is used, so that when the mold is open a complete shot includes not only the parts and runners, but also the cull disk.

Other equipment

There are two general types of preheaters used to precondition thermosetting compound before it is compression or transfer molded. One is the oven type, which gains its heat either from steam coils circulating hot air, or infra-red lamps. This type of preheater also doubles as a predryer.

The second type of preheater operates on the dielectric principle; that is, it makes use of the dielectric constant of preformed molding compound which causes the material to heat uniformly throughout its mass when it is used as the dielectric of a condenser. Standard high-frequency preheating equipment of this nature is available in varying capacities up to 15 kw., which size will raise the temperature of 12 lb. of thermosetting material from ambient temperature to 250° F. in one minute.

EQUIPMENT FOR EXTRUSION

BY ALBERT A. KAUFMAN* and FRANK R. NISSEL*

Today's improved extruder designs have been influenced to a decisive extent by the following four factors:

1) Extensive work has been done on the theory of plastics extrusion, and especially on extruder screw design. This has brought to an end a period of trial and error in the designing of equipment for extrusion.

2) Extrusion has developed broadly and entered fields not originally its target: namely, film and sheet extrusion, coating, and

* Prodex Corp., Fords, N. J.

References were prepared by the editors.

Recent Developments were excerpted by the editors from MODERN PLASTICS, Oct. 1956 through July 1957.

laminating, as well as various processing phases connected with compounding.

3) Wide field experience has resulted in a more critical economic analysis of machine performance. More production per invested dollar, lower operating costs, easier start-ups, and less maintenance have become more important factors.

4) The increasing scarcity of skilled personnel for operation and maintenance has resulted in more fully automatic control features and better instrumentation.

Machine construction

Basically, the extrusion machine consists of a stationary cylinder within which a closely fitted screw is rotated. Some machines use two or more screws. Material is conveyed continuously from the feed opening to the die orifice. There are a great many variations in the manner of driving the screw, absorbing its thrust load, and mounting the machine components. The following is a brief review of the major designs.

Gear transmission

Since extruder screws usually turn at speeds lower than those of the motor drives, it is necessary to use a gear reducer. These are built in several forms:

a) *Herringbone:* The transmission loss of herringbone gears is only 2 to 4 percent. The units are very durable, but are the most costly type.

b) *Helical:* Efficiency is about the same as that of herringbone reducers, but there is an axial thrust on the shaft bearings. With properly designed bearings, helical gear transmissions are well-suited for extruding machine drives.

c) *Worm:* Transmission loss is 10 to 25% and there are heavy axial thrusts on the worm bearings. These units are popular because of their low cost, but this is offset by the higher cost of a larger motor and its increased cost of operation for the same output.

d) *Chain and sprocket:* The cost of this transmission is very low, but it is not generally considered to be suitable for extruder drives because of its irregular power transmission characteristics.

A versatile extruder transmission must be capable of delivering the full motor horsepower over a wide screw speed range, so that a variety of compounds and different shapes can be run at high efficiency. A 2:1 full-horsepower speed range is desirable. Since gear transmissions have load ratings directly proportional to their speed—i.e., the rating decreases with the machine speed—the gear reducer should have approximately twice the motor rating. Extruder trans-

RECENT DEVELOPMENTS

Designed to impart gloss and improve the physical characteristics of thermoplastic sheets, the sheet glazer is most conveniently used in conjunction with an extrusion train. The underside of the sheet is chilled as the sheet moves on liquid-cooled rollers while the top face is radiantly heated to the flow temperature. Over-all length is 50 inches. *Goulding Mfg. Co., 2929 River St., Saginaw, Mich.*

An auxiliary extruder with a screw 1.25 in. in diameter by 12 in. long is especially designed to provide a small sidestream of melt of a second color in an extrusion where the main stream is furnished by a bigger machine. Several such auxiliaries can be used to achieve many color effects. Such products as multicolor welting, belting, tubing, etc., are easily made. *Thermoplastic Processes, Inc., 1949 Valley Rd., Stirling, N. J.*

The Rolis line of extruders, ranging in size from 1.5 to 4.5 in. in diameter, are said to be designed for durability. The barrel is electrically heated and water cooled, for fast response, but oil-heated cylinders are available. The chrome-plated screw has an L/D ratio of 20:1 on the standard-length machine in each size class. *Rolis Inc., 1240 E. 14th St., Brooklyn 30, N. Y.*

The Foster-Wucher W700 consists of an extruder and a turntable containing multiple molds. The extruder drive is connected to the screw, through a magnetic clutch, which is engaged only when a mold is indexed to the nozzle. The extruder then fills the mold and is stopped, the turntable indexes the next mold, and the last-filled mold cools as it proceeds around the circuit. Since injection pressure is relatively low, molds can be made of cast aluminum or zinc alloy. Screw diameter is 4 in., length is 30 in., speed ranges from 140 to 280 r.p.m., drive horsepower is 13. Most of the plasticating is done by viscous working. *International Vulcanizing Corp., 104 Brookline Ave., Boston, 15, Mass.*

A new center-fed cross-head sheeting die is said to be suitable for extruding most thermoplastics. It consists of an adapter, the manifold, a restrictor bar, a "flow chamber" and one set of adjustable die lips. Wide-land lips are recommended for thicker gages, narrow-land lips for thinner gages. The die is available in slit lengths ranging from 26 in. to 54 in., with thickness adjustments ranging from 10 to 190 mils. It is fitted with Chromalox heaters. *Johnson Mfg. Co., 229 S. Main St., Chippewa Falls, Wis.*

The Series 700 multiple-knife cutters are designed primarily for cutting cold plastics extruded in rod form (spaghetti) at high linear rates. The throat entrance is approximately horizontal and the width may be 5.6, 9.6, 11.6, or 13.6 in., ±0.1 inch. The rotating element contains 24 cutting blades mounted in such a way that the cutting action resembles that of a reel-type lawn mower, i.e., one end of each blade reaches the fixed (or bed) knife before the other end does. This distributes the working load, reducing shock to blades, mountings, and transmission. *Taylor, Stiles & Co., Riegelsville, N. J.*

missions require a service factor of 1.25 (A.G.M.A.); therefore, a 40-hp. load requires a reducer rated at 50 hp.

Thrust bearings

The extruder screw exerts an axial pressure toward the feed end which is roughly equal to the melt pressure at the die, or about 2000 p.s.i. A heavy, perfectly aligned, and well-lubricated thrust bearing must be provided to absorb the load.

Feed section

The feed section is usually a sturdy part which supports much or all of the cylinder weight through a flange connection. The feed opening may be round or rectangular, and can be either centered above the screw or tangential. The opening should be large enough to avoid bridging of materials. Feed sections are generally jacketed for cooling to avoid adhesion of some polymers to the feed-opening throat.

Cylinder

The extrusion cylinder consists of a precisely machined steel tube or forging. For uniformity of temperature, it is best made of a single piece without flanges. A variety of internal surfaces have been used to provide good wear resistance toward the screw and compound. Nitriding, flame-hardening, and chrome plating have largely given way to Xaloy which has the best all-around properties for most materials.

The screw

The screw conveys the material forward from the feed opening to the die. The material is heated to a melt and compressed with the elimination of much air. The screw should provide a uniform and high output rate against the back pressure provided by the die.

Extruder screws usually have three working zones: 1) material pick-up and initial transport; 2) compression and heating to a state of fusion; 3) pumping at a constant rate toward the die (metering section).

Extruder screws have been the subject of extensive theoretical study, and much of the theory has been substantiated in production experience. Basically, the effective output rate of an extruder is equal to the drag flow minus the pressure back flow minus the leakage flow. The drag flow is the forward motion of material provided by the dragging action of the barrel on the melt in the helical channel of the screw. The back flow is the reverse flow of material within the screw channel caused by the back pressure of the die restriction. Leakage occurs between the barrel and the thread lands. It is usually negligible. Calculation of each of these three components of output permits the design of highly productive extruder screws.

A breaker plate, often used in an extruder between the cylinder and the die, serves to support screen packs which filter the compound and is thought to aid in homogenizing the material.

Length/diameter ratio

The effective length/diameter ratio (L/D) of an extruder is defined in the following terms:

L: Length of cylinder from front end of feed opening to front of cylinder.

D: Inside diameter of cylinder.

This ratio is of considerable practical importance since longer machines give higher outputs and better uniformity, with resulting closer tolerances in the extrudate. In the past few years the "standard" L/D ratio has increased almost twofold to about 20.

Temperature control

Plastics extrusion requires precise and quick-acting temperature control. Both heating and cooling are necessary at the present stage of technology. There are three basic temperature control systems.

1) *Electrical:* Here the cylinder is encased in tightly fitting electrical heating elements governed by automatic feedback controllers. Three-position temperature controllers permit fully automatic temperature control with air blowers or evaporative cooling. Water cooling by coils or jackets has been found undesirable.

2) *Fluid:* Here the cylinder is jacketed and a hot fluid is circulated. Water, oil, Dowtherm, and Ucon are commonly used. The system is very effective, but the initial and maintenance costs are higher than those of electrical systems. Additional heat exchangers provide cooling.

3) *Steam:* Here the cylinder is surrounded by a steam jacket and is controlled by a simple steam-pressure regulator. High pressures are needed to get high temperatures.

Motor drives

For maximum flexibility, a continuously - variable - speed drive should be provided. The following factors are important:

1) Good speed regulation. Speed regulation is the ability of a motor drive to maintain its pre-set speed regardless of load. Motors with poor speed regulation tend to cause output rate fluctuations, and sometimes even cause pulsations with every screw revolution. About 2% change in speed from no load to full load is considered ample for critical applications.

2) Wide speed range (1.7:1) at full horsepower.

3) Remote speed control. This is highly desirable from an operational standpoint, so that an extruder may be controlled from a point near the die where the effect of speed changes can be observed.

Not all the available drives fulfill the extruder-drive requirements equally well. The following is a survey of drive types:

1) AC-DC drive. Here a motor-generator set provides direct current to drive a DC motor. This drive has excellent speed regulation when a feedback regulator is used. It is available with a wide full-horsepower range. Speed range at reduced horsepower is usually about 12:1. It is the costliest type of drive.

2) Magnetic clutch drive. This drive uses a single-speed AC motor with a variable magnetic coupling. Speed regulation is excellent when feedback regulation is provided. This system is available with a wide full-horsepower range, and can be operated from zero up to full motor speed. It is considerably less costly than AC-DC drives in the higher horsepower ranges.

3) Brush-shifting AC motors

can be obtained with good speed regulation, but have only constant-torque characteristics, i.e., horsepower output is low at low speeds. The usable speed range is only 3:1. These drives are widely used in Europe, but in the U.S. they are almost as costly as the much superior AC-DC drives and offer no advantages.

4) Mechanical speed variators. Here a pair of conical sheaves or gears are linked with a special belt or chain. The drive uses a single-speed AC motor. The speed range is about 5:1, but speed regulation is only fair (about 8%) and output power falls with falling output speed. Units up to 50 hp. are available and they are widely used because of their low cost.

5) Gear shifting. This drive has been used in some European designs in conjunction with single-speed AC motors. Speed change in steps is generally undesirable for starting up and operation.

Dies

Much work has been done on improving the precision of extruded products by better die design. Besides the standard types of dies for the extrusion of shapes, many specialized dies have been developed for the extrusion of film, sheeting, and pipe. Rheological analyses of sheet and film dies are progressing to the point where heat-sensitive materials, such as the vinyls, will soon be extruded in direct competition with calendering. Cooled-mandrel pipe dies are becoming standard in most installations. Wire coating and other continuous coating operations are generally performed on cross-heads where the material to be coated passes through a head which is at right angles to the extruder center line. A new development is the 30° cross-head which permits straight-head, cross-head, and cooled-mandrel pipe extrusion, all in the same direction and with a minimum of hot material inventory and deflection.

Take-offs

A variety of take-offs accommodates different types of end products. In each case it is the object of the equipment to cool the product while maintaining or improving its dimensions and appearance. The output of an extruder is frequently limited by inadequate take-off equipment.

Variable-speed conveyors with or without water cooling are widely used for extruding tubing, tapes, and profiles.

Wire and cable is usually water-cooled and is pulled off with capstans onto reels. Automatic change-over and speed control devices are available for continuous high-speed operation. More recently a caterpillar-type pull-off has been used for large-diameter cable and pipe. This offers strong positive traction without distorting the cable.

In the extrusion of sheet and film, highly developed haul-off units not only cool the product, but also improve the surface finish. Some can even overlay a laminate. Another type of take-off is widely used for the extrusion-coating of paper, etc. These take-offs are usually provided with automatic shears, edge trimmers, and stackers or wind-ups. Some surpass the extruder in cost and complexity. Beta-ray and other precision gages are becoming common for continuous product inspection and control.

Tubular film is made by inflation or drawing over a cooled mandrel.

EQUIPMENT FOR LAMINATING

BY G. R. ECENBARGER*

Equipment for producing laminated materials[1] is quite varied but, in general, falls into four categories: 1) impregnating and drying equipment; 2) cutting or sizing equipment; 3) pressing and laminating equipment; and 4) fabricating and finishing equipment.

Impregnating and drying

The impregnation of raw cloth or paper stock is performed in equipment designed to maintain the proper ratios of resin impregnation and advancement of cure of the contained resin, depending upon the ultimate end use of the finished product.

The base paper or cloth, which is usually received in roll form of varying widths, is mounted on an unwind stand and threaded through adjustable tension rolls and around a dip roll immersed in liquid resin whose viscosity is controlled by solvent content or temperature. The wet stock then passes between heavy steel rolls, mounted so that clearance is accurately adjustable within 0.001 inch. These driven rolls uniformly distribute the resin through the web and squeeze out excess resin. In some cases, wiper bars are used for this purpose, either alternatively or in conjunction with squeeze rolls. The wet web is then conveyed on a cross-slat conveyor through a long tunnel dryer.

The treated and dried material is cooled in a cold-air circulating section of the dryer just prior to emergence, or by passing the material over water-cooled rolls, which may also serve the purpose of pulling the material through the oven. The treated material is then wound on either cores or drum winders driven by friction clutches, adjustable to maintain tension on the material and to ac-

Recent Developments were excerpted by the editors from MODERN PLASTICS, Oct. 1956 through July 1957.

A 2200-ton laminating water-hydraulic press has a platen area of 80 by 38 in. and 10 between-platen openings. The standard model operates off the customer's existing accumulator system, at 2500 p.s.i. (max.) but a self-contained oil-hydraulic system will be furnished if desired. The 11 hot plates are cored for steam, the cooling plates for water. Daylight of each opening is 3.5 in., and when the press opens each platen returns to a given position. This permits using a specially adapted elevator with the press that greatly reduces unloading and loading time. Maximum daylight is 77.8 in., stroke is 36 in., and the rams are 34 in. in diameter. *Birdsboro Steel Foundry and Machine Co., Birdsboro, Pa.*

A machine that combines the forming and laminating operations in making countertop bends is rugged but simple in construction. The built-in heater consists of two rod-type elements totaling 15 ft. in length. Sheet up to 12 ft. long can be handled in any width. *Trinity Industries, 2910 Bay Rd., Redwood City, Calif.*

A continuous postforming machine for laminates, particularly Formica, utilizes dielectric heating in rolling angles from flat strips of laminates. The machine is capable of producing angles 1 by 1 in. minimum to 4 by 4 in. maximum, up to 10 ft. in length. Operation is said to be completely automatic. The laminate is heated to about 300° F., formed by rollers, and cooled to set the shape. It is possible to bend $\frac{1}{16}$-in.-thick Formica, for example, to a $\frac{3}{32}$-in. radius, with no springback, at rates of about 20 ft./minute. *Faratron, Inc., 4447 Union Pacific Ave., Los Angeles 23, Calif.*

complish the winding of a tight roll. In some cases the stock will be sheared to size and collated directly from the treater, instead of being wound into roll form. For this purpose, conventional shearing equipment of either the stationary or traveling type is used, synchronized with the speeds of the treater.

Recently, to get better uniformity, beta-ray gages have been used as a measuring device.

Cutting and sizing

Conventional paper cutting equipment is used for cutting material from rolled-up webs. Rotary cutters and stackers, slitting equipment capable of handling one to six rolls simultaneously, and trimming shears, either power- or hand-operated, are used. To make macerated stock, the material is fed through rotary fly-knife cutters that reduce the stock to irregular pieces.

Pressing and laminating

Pressing of laminated sheets is performed in high-pressure hydraulic presses. These presses are capable of exerting up to 2000 p.s.i., over surface areas up to 50 sq. feet. This is massive equipment and very often, in the cases of 10- to 15-opening presses, may weigh as much as 200 tons and stand three stories high. The larger presses will have as many as eight to ten 24-in. hydraulic cylinders to distribute pressure uniformly over the entire pressing area.

The press platens are usually 3 to 4 in. thick, and are channel-drilled or cored for steam and water to provide alternate heating and cooling cycles. These platens, with the press in the open position, are supported on stepped ladders to maintain a spacing of 3 to 5 in. to accommodate the unpressed build-ups. To allow for movement of the platens as the press closes, flexible metal hose or rotating joints connect the individual platens to steam, water, and waste headers. The laminating process requires uniform heating of the press and contents. This is done by passing steam or hot water under controlled pressure through the channeled platens. When curing is complete, cold water replaces the heating medium, and the press is cooled as quickly as possible. Control of the heating and cooling cycles may be performed manually, but the trend is toward automatic cycling and control.

Rods

Rods are produced on special equipment that winds a continuous strip from the roll onto a small-diameter chrome-plated mandrel. The mandrel is supported between three heated and driven rolls under pressure, in order to soften and compactly bind the laminating material. Upon withdrawal of the mandrel, the resulting tube is further cured and densified to a rod in a heated mold under hydraulic pressure. Centerless grinders then reduce the rod to the required size and finish.

Noncircular rod forms, used as wedges, motor and generator commutator spacers, and other special applications, are produced by molding stacks of flat strips in multi-cavity molds. The cured moldings are parted with gang saws and a final milling or finishing operation removes flash.

Tubes

Tubes are produced on equipment similar to that used in the molding of rods as described above, except that a chrome-plated mandrel of a diameter equivalent to the inside diameter desired in the finished tube is used. The mandrel is not withdrawn until curing is complete.

Molded shapes

Molded shapes for special applications are produced in molds with chrome-plated cavities. It is usually necessary to premold macerated, treated cloth stock in order to reduce bulk. This premold is then further densified and cured in a subsequent compression molding operation, which will produce the final dimensions and finish characteristics. Several premolds can be combined into one final molding, and complicated shapes, possessing high impact and structural strength, can be produced.

With the exception of certain

special laminations incorporating glass or other ceramic fibers, which must be processed with abrasive cutting tools and equipment, the bulk of laminated products may be processed on conventional wood- and metal-working equipment. Either saws, or shears, equipped with high-speed steel or Carboloy blades, may be used to trim and shape sheets up to ⅛ in. thick; heavier materials are handled almost entirely by sawing.

Rotary shears are used for producing strips from the thinner materials in large quantities, as required for automatic punch press operation. Drum sanders are used to size boards and sheets to close specifications and to produce surfaces adaptable to gluing.

EQUIPMENT FOR COATING

BY R. C. STURKEN*

One of the more important uses of plastics and resins is in the form of coatings applied as thin films to other materials.

For the application of plastics coatings to flexible webs of material there are several basic methods which can be used. The first and oldest involves the use of a solvent solution, dispersion, or water emulsion of the resin. The second method involves melting the plastic material to a liquid state of moderate viscosity and applying it directly, without dilution, as a hot melt. The third method involves the direct extrusion-coating onto the web.

A wide variety of coating machines has been used for applying solution, dispersion, emulsion, and hot-melt coatings. The same equipment can be used for all of these materials in the low-to-medium viscosity range, except that for hot-melt materials the coating rolls, pans, and other parts are heated.

Perhaps the oldest and simplest type of coater is the knife coater. This coater includes a coating knife which scrapes against the web and meters the amount of plastic material being applied. Four arrangements of knife coaters are shown in Fig. 1, right. This equipment is simple and inexpensive but does not give accurate control of coating thickness and is subject to streak formation.

Roll coaters

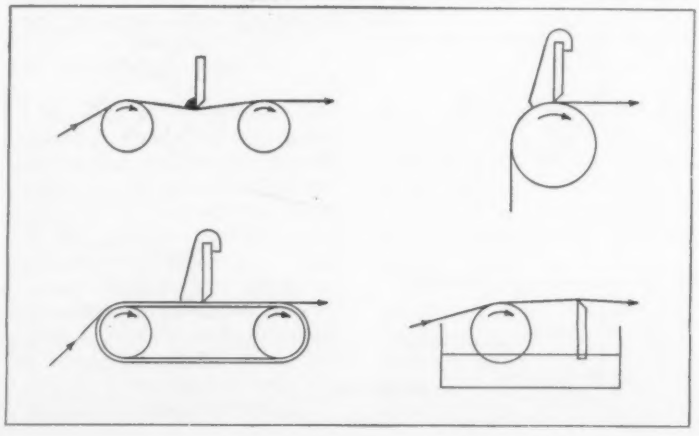
Various types of roll coaters can be used for applying plastic materials to webs. Of these, the reverse roll coater is the most accurate and at the same time the most versatile. Various arrangements of rolls used in reverse roll coaters are shown in Fig. 2, p. 904. On this machine the coating thickness is accurately metered between two precision-ground chilled iron rolls, and the thickness has been found to be relatively independent of viscosity, speed, web tension, and web surface.

Air knife coater

The air knife coater, also known as the air coater or air brush coater, has recently been finding increased usage in the application of water emulsions and dispersions of plastics materials. In this type of machine, a coating is applied by means of a roll and is then smoothed and doctored by a blast of air from a precision slot.

The development of film-forming water dispersions of high solids content of such materials as polyethylene and polyvinylidene chloride in Europe has led to the adaptation of the air coater for these products to a greater degree than in the United States where such formulations are not yet available. This process has the advantages, of course, of not using expensive or flammable solvents as diluents.

Gravure print coater



Another specialized unit for applying very thin coatings is the gravure print coater. This machine is designed so that it picks up the coating with a doctored engraved roll and then prints this coating on to the web. This type of unit is very accurate but is limited to thin coatings and is relatively inflexible for producing various coating weights.

Drying

On all coatings containing water or organic solvents, a drying tunnel must be used after the coater. The heat can be furnished by means of recirculated hot air or by various types of infra-red heaters, or a combination of both. On plastisol coatings containing no solvent, it is merely necessary to heat the material to fuse the coating, while in the case of hot-melt coatings the material is cooled with either air cooling, water-cooled rolls, or with a combination of both.

For the direct application of high-viscosity film-forming plastics to continuous webs, the so-called direct extrusion coating or extrusion-lamination process has

Recent Developments were excerpted by the editors from MODERN PLASTICS, Oct. 1956 through July 1957.

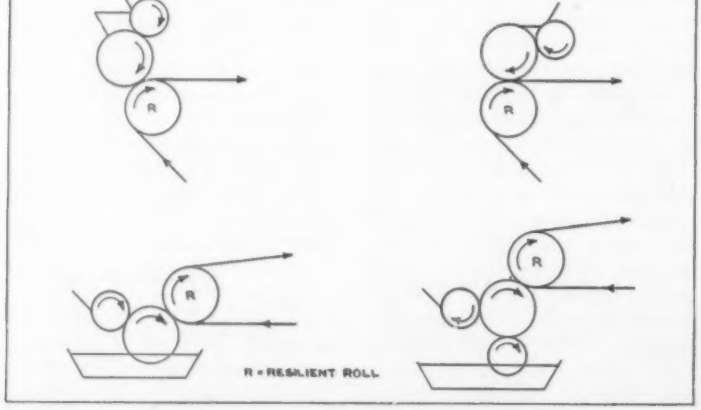
Bench-type coater is designed to coat sheet materials such as plastics, plywood, fabrics, etc., up to 1.5 in. thick, with paint, adhesives, and so on. Several models are available: there are single top coaters, bottom coaters, and two double styles in lengths from 8 to 52 inches. A uniform-thickness coating can be applied at rates up to 3800 linear ft./hour. *L. R. Wallace & Co., 191 N. Pasadena Ave., Pasadena 3, Calif.*

The Whirlclad process consists of immersing (hot) objects to be coated with plastic into a fluidized bed of specially formulated polymer and metal powders. The sensible heat of the object will in many cases be sufficient to fuse a continuous plastic coating over its surface. Where it is not, post-heating completes the fusion. Metals, ceramics, glass, and wood articles may be so coated. Tanks range in size from 7 in. in diameter and 8 in. high to rectangular ones 39.5 by 39.5 by 79 inches. Advantages of the process over melt and solution coating are: superior penetration of coatings into contours, no beading, no thinning. *Polymer Processes, Inc., 125 N. 4th St., Reading, Pa.*

Available in four models, the Walco bench-type coater is designed to coat sheet materials, including plastic sheeting, with paints, adhesives, etc. All the rolls —some steel and some rubber— are power-driven by a ¼-hp. motor; the rubber rolls are available in neoprene, thiokol, or Hycar, in lengths from 8 to 52 inches. Grooved rolls are available for use with heavy adhesives. *L. R. Wallace & Co., 191 N. Pasadena Ave., Pasadena 3, Calif.*

come into wide usage during the past five years. This process has found its largest use in the manufacture of polyethylene-coated paper, cellophane, and aluminum foil.

Extrusion-lamination



In the extrusion-lamination process, the resin is first extruded in an essentially standard extruder. Because high extrusion temperatures (600° F. or higher in the case of polyethylene) have been advisable in order to obtain maximum adhesion of the coating, the electrically-heated extruder is the most widely used in this industry.

An extrusion-lamination machine, as shown in Fig. 3, p. 905, discharges the plastic into a horizontal sheeting die which forms the resin into a thin film. The hot extruded film is laminated directly onto the paper or other web to form a continuous coated sheet, with a specially designed film laminator. This unit consists of a water-cooled roll and rubber pressure roll located directly beneath the sheeting die.

The water-cooled roll is specially designed so that all of the heat can be removed from the plastic on a single roll rather than requiring a series of rolls; otherwise, the coating will adhere to the roll. The outer surface of the roll can be given a highly polished chromium-plated finish or a matte finish, depending upon whether a glossy or dull coating is desired.

As in the manufacture of plastic film by extrusion through a flat sheeting die, the edge of the film thickens when it is stretched after leaving the die. This condition makes it necessary to trim this heavy portion from the coated material before it is wound up. With the techniques originally used it was necessary that the web be wider than the extruded film to prevent adherence of the plastic to the rubber pressure roll. This resulted in the production of considerable waste which could not be reclaimed. Recent techniques have been and are being developed, however, using special silicone rubber compounds and special roll designs, so that the film can be extruded wider than the web. Under these conditions the heavy edge can be trimmed off as pure plastic and can be reclaimed.

Fig. 2: **Reverse roll coaters; coating thickness is metered between rolls.** (Sketches in this section, Frank W. Egan & Co.)

Coating rigid materials

Many paints, varnishes, enamels, and lacquers contain synthetic resins and plastics materials, and hence films of these materials can be considered plastic coatings. They can, of course, be applied by the well-known conventional methods of brushing, spraying, and dipping, and will not be treated further in this article.

More recently, however, techniques have been developed for direct application of thermoplastic materials to metal surfaces without the use of solvents or diluents. Such processes will, of

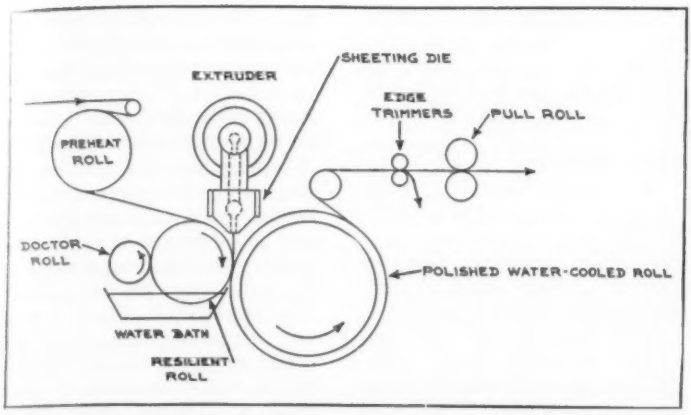


Fig. 3: Extrusion-laminating machine; extruder feeds film to laminator unit

course, have important economical advantages in cost of application and in ability to produce thicker coatings, and are particularly advantageous for plastics which cannot readily be dissolved.

The principal methods used for direct application of plastic coatings include *direct fusing of powdered resin* and *flame spraying*.

In the application of fused powder coatings, the plastic is first reduced to a finely powdered state suitable for fluidizing. A charge of powder is then fluidized by means of compressed air in a fluidizing chamber. The object to be coated is heated in a conventional oven to a temperature above the melting point of the plastics (400 to 500° F. in the case of polyethylene). It is then immersed in the fluidized bed of plastic powder for a period of 5 to 20 sec., depending upon the thickness of coat desired.

The coated object is then generally given a post-heating treatment in the oven to complete the fusing and leveling of the outer surface of the powder deposit. Thicker coatings can be obtained by repeated heating and dipping of the article. Prompt quenching in water is advisable since plastics are susceptible to oxidation.

Flame spraying

In the case of objects and surfaces which are too large to be immersed in a fluidized bed, flame spraying of powdered plastic is used. The surface to be coated should again be preheated before it is ready to receive the plastic.

The plastic is reduced to a powder form for feeding to the spray gun. In one type of spray gun, a suction is generated by means of a venturi, and this picks up the powder which is fed into the induced air stream from a hopper through an orifice. In another system, the powdered plastic is fluidized and is fed under pressure from the fluidized bed into the spray gun.

A flame is generated in the spray gun by means of compressed air and acetylene or other fuel gas, and the plastic powder is sprayed through this flame onto the surface being coated.

This same spray gun may be used as a torch for preheating the article to be coated, in which case a neutral flame is used. When the actual coating is being sprayed, however, a reducing flame must be used in order to prevent oxidation of the plastic being used as the coating.

The plastic powder is partially melted as it is propelled through the flame and the fusing is completed when it strikes the preheated surface which is being coated.

EQUIPMENT FOR CALENDERING

BY KENDRICK J. GOOCH*

The degree of quality and economy obtained in calendering plastics film and sheeting depends largely on the amount of careful planning entering into the design of the complete calender train. Material should flow from resin storage through the processing operations to packaged rolls of finished goods with a minimum of human effort. The size of related train components, e.g., mixers and mills, conveyors, calendering rolls, etc., should be in proportion, both to production requirements and to each other, so as to be used at their maximum rate of output.

Primarily, the process of calendering is used to densify the resin and to produce a desired thickness and surface finish on a given film or sheet of material. This operation is performed be-

* Asst. Div. Engineer, Mill and Calender Div., Farrel-Birmingham Co., Inc., Ansonia, Conn.
References were prepared by the editors.

tween two or more pairs of rotating beams called rolls. Each roll pair constitutes a rotating die through which the material is either drawn or extruded, or both.

Mixing the resin

The initial step in the calendering operation is the mixing of the resin. Various types of intensive mixers and mills are available that can be arranged to suit specific production requirements.

The tower type of preblending arrangement, for example, is one that requires a minimum of material handling. Resin is blown through piping or elevated in bags to high storage bins. It drops from the bins onto shaking screens, flows by gravity through sifters and into traveling weigh hoppers which feed the blenders, and from the blenders pours into weigh hoppers located directly above a Banbury mixer hopper door.

If both film and sheeting are to be produced with the same calender train, good results can be obtained by using a setup such as is shown in Fig. 1, below. In this arrangement, two 3A Banburys are installed with the hoppers facing each other. One operator can thus control both units for producing sheeting, and a single unit can be used at maximum capacity for the thin-gage films.

To obtain a wide range of finished gages, two mills can also be used. One of these mills should be mounted directly under a Banbury. The second should be opposite the first, so that the adjusting screws are on adjacent sides and one operator can control both mills. Material is carried by strip-feed conveyor (a narrow, flat-bed, hugger-type unit) from the first mill to the second, and then to the calender feed bank. The calender can also be supplied directly from the first mill.

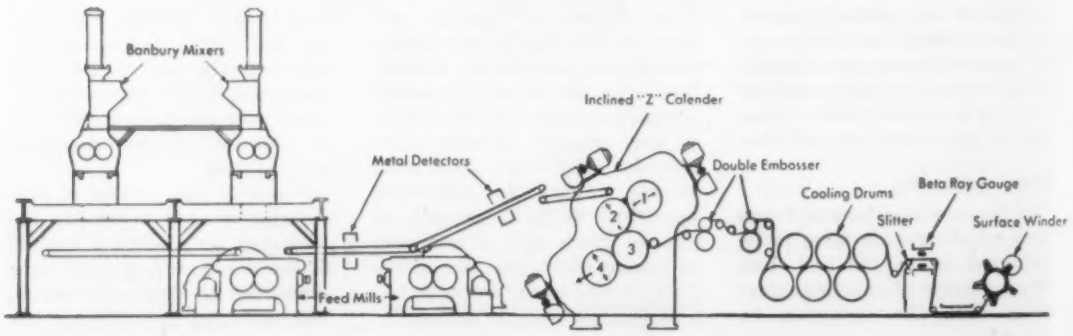
Metal detection

In setting up calendering equipment, it is important that provisions be made to keep metal-contaminated material from being fed into the calender where it would mark up the calender rolls.

When using the strip-feed conveyors described above, small-gap, sensitive metal detectors can be easily installed along these conveyors. Strip conveyors can also be designed to cut out and discard automatically a length of material containing a metal particle with a minimum of lost feed to the calender. This is essential for high-speed calendering.

A more positive means of metal elimination is obtained by using an extruder with a strainer-type head. This method is relatively expensive since a large unit having an adjustable-speed drive, synchronized with the calender speed, is required. Moreover, the strainer removes all solid particles, not just metallic objects. Where surface finish is important, the higher initial cost is offset by the savings effected by eliminating possibilities of roll damage.

Calendering rolls



The latest trend in plastics calendering is toward calenders designed for higher roll temperatures, greater roll separating forces, and a wider range of available friction ratios.

Several types of roll arrangements are available for selection on the basis of ease in threading, accessibility of the rolls, and general convenience. The "Z" and the inverted-"L" arrangements are standard in the industry. A recent development is the inclined "Z" which provides a clear and short path for material travel, permits easy accessibility for coating fabrics, and enables the embosser or other attachment to be placed close to the pick-off roll. As shown in Fig. 1, below, this calender incorporates the necessary feature of crossed-axes on the No. 4 roll, with the material being taken off the No. 3 roll instead of the No. 4 roll, as with previous calender roll arrangements.

Few plastic calenders are designed to make only a single size of sheeting from a single stock. Usually, the maximum flexibility is desired so that thin films and heavy sheeting can be produced to satisfy market requirements. This, in turn, means the rolls will be subjected to a wide range of separating forces. These forces bend the rolls, changing the shape of the aperture between them. If some compensation for this bending were not made, the sheet thickness would vary considerably over its width. To keep the sheet flat, two techniques of compensation are used. In one—roll bending—an opposing bending moment is applied to the rolls. In the other—roll crossing—one roll axis is crossed slightly with respect to the other by causing it to pivot about its midpoint of length.

Several calenders recently built are equipped with individual motor drive for each roll. This is accomplished either by connect-

Fig. 1: Typical calendering setup designed to be used when both film and sheeting are to be made with the same calender train

ing each roll directly to a gear-motor through a universal spindle, or by using a semi-uni-drive between the gear motors and the spindles. Both of these arrangements provide a wide range of roll friction ratios which are advantageous for the newer types of plastics compounds. Since these compounds require high power at slow speeds, calenders, driven by motors having a low base speed, have been designed for calendering rates up to 100 yd./minute.

Material coming from the calender should have a reverse wrap around closely spaced carrier rolls to prevent pull-down in width. Free-turning rolls with spindles driven to eliminate friction are required near the calender.

The recent trend in post-calender embossers is toward double or turret-type units in order to provide a quick change of pattern. The type of embosser required depends on the embossing pressure and whether or not the rubber roll, as well as the embossing roll, must be frequently changed. High-pressure embossing at top calender speeds requires a heavy-duty driving motor.

Cooling rolls are usually driven in groups of three for best speed control. The number required depends on the heat to be removed and this is proportional to the sheet thickness and production rate. Slow-speed film calenders may have only three cooling rolls, whereas high-speed sheeting calenders will have nine or more.

Many calenders now have two-speed, motorized roll adjustment with the low speed designed for use with automatic gaging. Beta-ray gaging equipment has now been designed to control not only the longitudinal and edge gage, but also the entire profile. In automatic profile control, the Beta-ray gage governs the roll-crossing or roll-bending equipment.

Calender wind-up

The type of winder is usually determined by the gage of material of primary interest. Film tensions are readily controlled on a surface-type winder. Large rolls of sheeting may be better handled on a two-arm center winder. For both types, the material should be cut off and started on the new roll as automatically as possible. Winders for coated fabric must have special cutters in order to cut through both plastic and fabric without reducing the calender speed.

Drilled rolls and circulating-liquid temperature control are an accepted part of almost all plastics calender installations. Now, mills, and in some instances Banbury mixers, are also commencing to be controlled in temperature by similar systems.

EQUIPMENT FOR MOLD MAKING

BY ISLYN THOMAS*

No matter how carefully a mold is designed, it will not produce satisfactory molded parts unless it has been constructed with the utmost care and skill. Molds and dies for the production of plastics parts are generally made of metal, with components produced by machining, hobbing, casting, electroforming, and metal-spraying.

In order to machine these metal molds, practically every type of machine tool may be used.

Auxiliary equipment

Many types of auxiliary equipment are necessary for making molds. Filing machines, hand grinders, tool grinders, welding machines, laps, and hardening equipment are among the items necessary for precision tool work. Hand grinders are used to add finishing touches to hardened molds.

One very important operation is hand filing of corners and curves which cannot be cut out with end mills. Since hand filing is naturally a slow, expensive operation, work of this nature should be held to a minimum.

To remove tool marks, holes and irregularly shaped depressions are smoothed by hand stoning with silicon carbide abrasive sticks of progressively finer grits.

Polishing machines consist of a stand that holds a small motor operating a flexible shaft to which may be attached polishing brushes or small grinding wheels of aluminum oxide abrasives.

Lap sticks, brushes, wood sticks, and felt bobs are used with diamond compounds to grind hardened or unhardened molds and bring them to a high finish.

Shapers and planers

Shapers: The shaper is a straight-line cutter of the planer type. It performs a large variety of operations, such as squaring up mold plates and making them symmetrical in shape and properly sized. The feed-motion of shapers may be given either to the cutting tool or to the work. When the cutting tool is moved, the machine is described as a travel-head shaper.

Planers: If a large enough shaper is not available for squaring up mold plates and cutting out large cavity blocks, a planer serves the same purpose. The fundamental difference is that planed work is bolted to the machine table which reciprocates while the tool remains fixed. Large planers will machine several surfaces simultaneously.

Lathes

The lathe, in the last few years, has undergone many improvements and transformations, thus widening its scope and very greatly extending and expediting its operations. Among a bewildering variety of lathes, many of which are specialized, probably the most familiar is the engine lathe, which, with special attachments, is known as the toolmaker's lathe.

Whereas a shaper or planer is used to form plane surfaces, a lathe is used to form pieces with circular cross-sections. Cutting

*General Manager, Newark Die Co., 20 Scott St., Newark 2, N.J.

Recent developments were excerpted by the editors from MODERN PLASTICS, Oct. 1956 through July 1957.

Moldtem, a new mold and die steel, is a chromium-molybdenum-vanadium alloy that comes prehardened and ready for use without further heat treatment. The hardness ranges from 302 to 341 Brinell. Moldtem is claimed to have maximum polishability and is easy to machine. A combination of chemical composition and careful quality control helps to eliminate the tiny pit-producing bubbles characteristic of many steels. These pits cannot be polished out or filled by plating. *Heppenstall Co., 4620 Hatfield St., Pittsburgh 1, Pa.*

Poly-Flex 100, a polymer-based mold compound in liquid form, has been developed for making flexible molds over plastics, wood, metal, clay, or wax patterns. The resin is mixed with a curing agent to give a low-viscosity liquid that molds very faithfully and cures in 4 hr. at room temperature. *Smooth-On Mfg. Co., 572 Communipaw Ave., Jersey City 4, N. J.*

Six new standard sizes of mold bases have been announced by DME. In all six, one dimension is 23.75 in., and all are available in a range of heights from 9.9 to 16.4 in. The remaining lateral dimension, for the six bases, is: 14.9, 16.5, 19.5, 23.75, 29.5, and 35.5 inches. Special features: clamp slots to save platen space, tubular dowels that leave more room for coring, stop pins that are welded to the ejector bar, and one-piece ejector housing. *Detroit Mold Engineering Co., 6686 E. McNichols Rd., Detroit 12, Mich.*

tools for lathe work are somewhat similar to shaper tools and are held in what is known as the tool-post. The tool-post is part of the carriage and is movable in two directions by means of screws.

The lathe will turn outside and inside surfaces and will cut both inside and outside threads. The lathes used in mold making range in size from small bench lathes for pin work to large ones for turning big dies, such as reflector molds, etc. The lathes especially designed for form and contour turning have all their speeds and movements controlled by individual electric motors.

Attachments available for lathes include internal and external grinders, milling attachments, special holders, and chucks.

Milling machines

Both vertical and horizontal milling machines are considered standard equipment in a mold making shop.

Vertical milling machines: Perhaps the most important of the milling machines for mold and die making is the vertical-spindle miller, available in many sizes and styles, from small hand-feed types to large multiple-spindle machines with automatic profiling and depth control equipment. The latter device automatically duplicates cavities of any shape, either from templets or from master molds. All varieties have a table which provides a longitudinal feeding motion. On some types, cross-feeding motion is available.

A two-, three-, or four-toothed cutter of the end-mill type fits in the milling machine spindle; it fits either directly or can be fitted by means of chucks or quick-change collets.

Rotary-head milling machines: The rotary-head milling machine embodies all the characteristics of the vertical milling machine plus many other features.

The rotary head, the spindle slide, and the transverse and longitudinal travel of the table provide all movements necessary to cut any profile that the draftsman can draw by the use of the straight-edge, protractor, and compass.

Saws

In the preparation of the various cavities and backing plates for the mold, steel has to be cut from bar stocks, special forgings, billets, or plates. The plates must be prepared for the machining of the cavities. In order to put them into the desired shapes and sizes, the following machines may be used:

Power hack-saws: The most commonly used machine is the power hack-saw, which is a motor-driven saw, larger than the hand hack-saw, with a blade of high-speed steel. This saw is used to cut tough alloy steels.

Band saws: The common band saw, which at one time was considered merely a woodworking tool, has now become a high-grade metal-cutting saw. Band saws are of two general types: 1) those with tilting tables for simple cutting and angles; 2) those that will also cut intricate internal or external contours. A simple welding unit built into this machine quickly butt-welds its blades, when they have been cut for internal work.

Cut-off machines

The abrasive-wheel cut-off machine cuts small-quantity lots with extreme accuracy and high speed.

A rubber-bonded abrasive wheel, rotating at exceedingly high speed, is mounted in a counter-balanced, vertically swinging head and is brought down on the stock by means of a straight, almost effortless pull.

By means of the abrasive-wheel cut-off machine, the bar stock, laid unfastened upon the machine table, can be cut to length within a few mils without raising burrs.

Torches: The acetylene torch cuts with a jet of flame and can be used for cutting symmetrical as well as irregular shapes from stock up to and over 12 in. thick, depending on the pressure in the gas bottle. This rapid type of cutting is used mostly on soft machine steel.

Duplicators

At one time the design and production of a mold was left to the skilled tool maker, who used the general-purpose equipment available to him. Today, experienced tool shops specializing in mold making must consider the quickest

and most economical way of producing well-operating, dimensionally correct molds if they are to meet competition successfully.

This change of attitude has resulted in the introduction of duplicating machines. They provide a means of producing identical cavities in multiple-cavity molds of regular form and contour but, for making large numbers of heavy blocks, the hobbing method described below is more economical.

There are three basic types of duplicating machines—manual, electric fingertip control, and automatic—all capable of two-dimensional or three-dimensional work.

In two-dimensional duplicating, the operator generally places both hands on the lever which controls the lateral movement of the duplicator table in any direction, thereby permitting the tracing stylus to follow precisely the shape of the master that is being duplicated.

For manual duplicating in three dimensions, the operator uses his left hand to control the vertical movement of both the milling cutter and tracer spindle, his right hand to direct the lateral movement of the duplicating table.

Electric-control types of duplicators have sensitive fingertip control which determines the cable movement. Controls can be set for either roughing or finishing.

Automatic duplicating machine: Actually a powerful horizontal milling machine in which up, down, and lateral movements are operated by electrically controlled power feeds, this machine may be used both to profile in two dimensions or to reproduce reliefs in three dimensions. In either case, a tracer passes over the master form and the cutter duplicates the path precisely.

Drill presses

Single-spindle vertical presses, the most common machines for drilling holes in molds, may be either bench or floor models. These drill presses are made in several sizes, ranging from small, highly sensitive, precision models to units that will drill 3-in. and larger holes.

Radial drill presses, although vertical, differ from simple "verticals" in that the drill is moved from one location to another in a piece of work. A *universal radial drill press* has an arm which can be adjusted to drill at almost any angle.

Horizontal drill presses are of considerable value to the mold maker for drilling water or steam lines. The horizontal press permits simultaneous drilling of many holes up to 40 in. or more in length.

Jig borers

A jig borer is actually a combination drill press and vertical milling machine. It allows locating and spacing of holes with extreme accuracy, and is used for laying out the cavities of the mold.

Grinding equipment

There are many types of grinding machines designed for various purposes.

Jig grinders eliminate makeshift methods of correcting holes after hardening. They do away with dowel gages and end blocks, because the hole location is obtained through accurate, hardened guide screws, and thus makes any additional corrections unnecessary.

Vertical rotary surface grinders, rugged and rigid, are used principally for preparing flat stock for subsequent fabricating operations.

Reciprocating surface grinders, also used for flat stock, hold the work magnetically to the table while it is made smooth and parallel after shaping and hardening.

Centerless-type grinders are used principally for external grinding operations on cylindrical work requiring a high grade of finish and extremely close accuracy.

Many sizes are available accommodating work up to 60 in. in diameter and up to 24 ft. in length. There are two styles within this range: plain and universal.

As a general rule, plain machines are sturdier and are usually designed for high production work; "universal" machines are designed for a wider variety of work, including face, angle, and internal grinding. Taper and shoulder work can be ground on either style.

Cutter grinders: In precision milling, duplicating, or engraving work, cutters must be reground as often as 20 times per day to ensure accuracy. Cutter grinders, designed for such sharpening operations, are provided with graduated dials and adjustments.

A *pedestal* or *bench grinder,* consisting principally of a motor with a grinding wheel mounted on each end of its shaft, is required equipment for sharpening small tools.

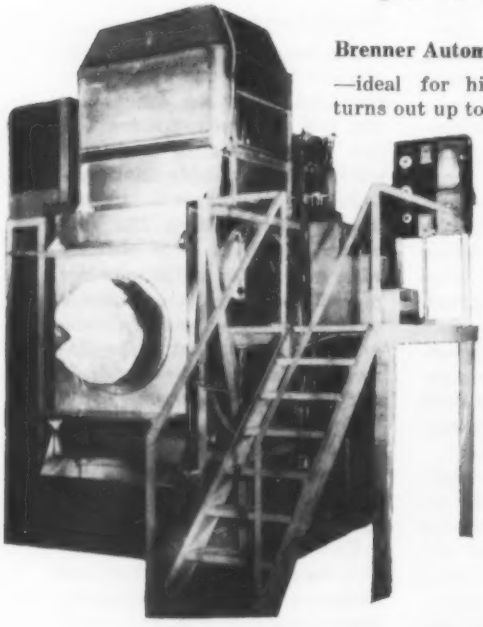
Individual or central dust collectors must be provided for dry grinders and operators must wear shields in order to protect their eyes.

Machine engraving

The engraving of master hobs and cavities in the early days depended solely on the ability and skill of hand engravers. Today many types of engraving machines are available using pantographic devices with motor-driven rotary cutters. The machines are built very sturdily with micrometer adjustment for precision work and are generally equipped with adjustable pantographic ratios so that the equipment can be adapted to hundreds of different applications.

There are two main types of engraving machines in use today —two-dimensional pantographs and three-dimensional pantographs.

Two-dimensional pantograph: For the engraving of letters and designs, a two-dimensional pantograph should be used. The operation is quite simple after the enlarged master templet or copy is set up in the copyholder. The tracer, guided by the machine operator, follows the copy. In addition to working on flat surfaces, these machines can operate on concave, convex, and spherical surfaces, provided the curvature is relatively uniform and not too great.



Three-dimensional pantograph: For engraving in three dimensions from enlarged models of any shape or contour, a three-dimensional pantograph is required,

which will also be capable of performing the work that is being done by a two-dimensional pantograph.

For three-dimensional work, a modeling bar is used. This bar, connecting the tracer spindle and cutter spindle, transmits the movement of the tracer as it passes over the contours of the model to the cutter spindle, reduction ratio being governed by the setting of the pantograph bars.

Hobbing presses

Hobbing is one of the best methods for insuring uniformity and economy in production of multiple-cavity molds and should be of great interest to all molders and mold makers. Owing to the tremendous growth in demand for hobbed cavities of all shapes and sizes, hobbing presses have increased in capacity from approximately 50 to 3000 tons and even more. A hobbing press is just a hydraulic press that is more sturdily built than ordinary presses because it has to deliver more concentrated force. Between its two platens is placed the mold blank, on top of which is placed the hob. To support the soft mold blank and keep it from spreading diametrically away from the hob while being formed, a hardened chase or hobbing ring is used. The ring is not necessarily round; it may be rectangular in shape.

On one-push impressions, the amount and location of relief is important; but it is on those impressions requiring two or more squeezes that the hobber's skill and experience, and the suitability of the hobbing press, really come into play. It takes only a few misguided seconds in a hydraulic press to ruin a hob on which many hours and many dollars have been spent. When hobbing is being considered it is wise to consult a good hobber before making either hobs or blanks.

Atomic hydrogen welding machines

Sometimes it is necessary to build up mold parts by the addition of metal. A cutter may take out more metal than it should, or a mold part may be worn or broken off in actual use. In order

to save this mold part, it has sometimes been found quite practical to weld with an atomic hydrogen torch.

Hardening equipment

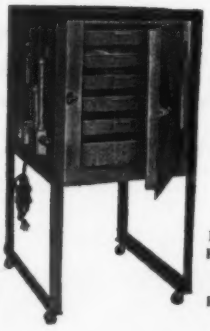
Practically all mold parts should be hardened before using. Equipment for this work should consist of at least one carburizing furnace, one annealing furnace, one tempering furnace, and a small furnace for odd jobs. All furnaces should be equipped with good recording and control instruments.

Liquid honing equipment

To speed up polishing of mold cavity parts, they are generally abrasive-blasted to remove oxidation and discolorations which have been brought about by the annealing, hardening, or carburizing operations.

This "liquid honing" is a modified form of impact blasting in which an abrasive, suspended in a liquid, is delivered to the blasting nozzle by means of a circulating pump. The suspension, shot at the work by 90 p.s.i. air pressure, gives the surface of the mold a satin-matte finish. A short polishing operation restores the desired luster.

Chrome-plating equipment



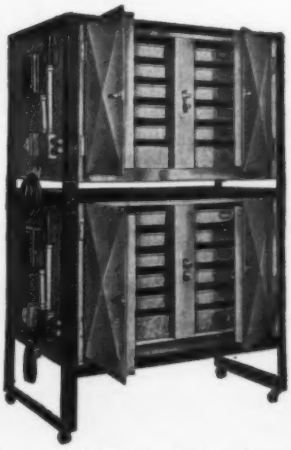
Chromium plating became an important factor in the tool industry when it was discovered that platings from 0.0002 to 0.05 in. thick would conserve steel by greatly increasing the life of hand and machine tools. Chromium plating gives the plastics industry the advantages of harder surface, less sticking, elimination of pitting caused by gases of reaction, reduction in breaking-in time, high finish of molded parts, and better flow.

Because of the plating characteristics of chromium, any defects in the mold surface are accentuated. This fact should be given serious consideration when setting up polishing procedures to assure good moldings.

Molds for such operations as vacuum forming, reinforced plastics molding, thermoplastic sheet forming, short-run pressure molding, etc., where mold and strength durability requirements

BROSITES OVENS and DRYERS

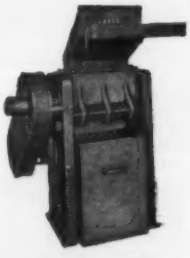
• SIMPLE AND FAST TO OPERATE



MODEL NO. 1
Single Door: Width 24½"
Five trays 15" x 22" x 2½"
Height 50"—Depth 28½"
Heating Element 1800 watts.
Thermostatic Control 100° to 300° F.

MODEL NO. 2
Double Door: Width 48"
Height 50"—Depth 28½"
Ten trays 15" x 22" x 2½"
Heating Element 3600 watts.
Thermostatic Control 100° to 300° F.

MODEL NO. 3
Double Decker:
Width 48"
Height 68½"—
Depth 28½"
Twenty Trays 15" x 22" x 2½"



Model No. 3 is two Model 2 units placed one above the other. They can be operated independently of each other and the top unit can be used in reverse position whenever desired.

RUGGED, made to last . . . EFFICIENT, economical to use

The trays are of such size and design to hold approximately 10 pounds of the average material when placed to a depth of about one inch. Special trays of expanded metal allowing greater circulation of heat can be supplied and are recommended for the preheating of pellets and other solid objects. For special uses the trays, or the entire unit if required, can be made of stainless steel, monel metal or nickel. Sturdy in construction, built of steel sheeting, carefully and thoroughly insulated with rock-wool insulation placed between the inside and outside shells of the dryer. Mounted on casters for easy movement from one location to another in the plant. Each unit is equipped with thermostat to automatically control temperature of the oven. A light indicates when unit is in operation.

EQUIPMENT FOR COMPOUNDING AND COLORING

In general, compounding and coloring thermoplastics requires at least four steps: 1) weighing ingredients, 2) mechanical blending, 3) plasticating the mixture, and 4) cutting the finished compound into usable particles. At least one piece of equipment will be required for each step. Not infrequently, where a particularly thorough mixture is desired, two types of equipment—a Banbury mixer and milling rolls—will be used for the plasticating step.

In some cases it may be possible to eliminate one or more of these four steps, with a corresponding reduction in the amount of equipment needed.

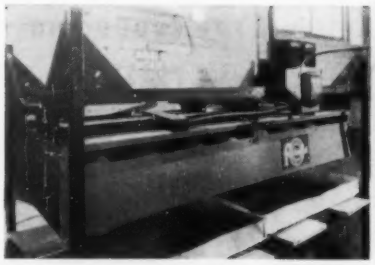
The choice of equipment for each of the four compounding stages will depend in part on the quantity of compound desired and the speed of production. The nature of the thermoplastic being compounded and of the other ingredients will also play a part in determining the type of equipment required for each stage. Finally, the form in which the compound is to be fed to the molding or extruding machine will affect the choice of equipment for final cutting.

Weighing equipment is re-

Recent Development excerpted by the editors from MODERN PLASTICS.

quired for the first step in any compounding or coloring operation, unless the desired proportions happen to be such that the batch can be made up from preweighed contents of bags, drums, or other shipping containers. Even in such a case, check-weighing may be desirable to assure accuracy.

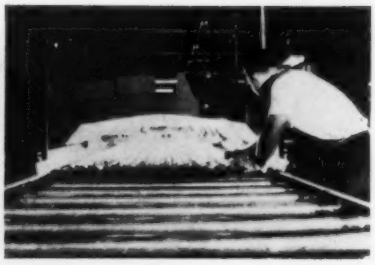
The type and size of scales used will vary widely with the nature of the operations. For the coloring of polystyrene crystal in a molding plant, small balances will generally be all that are necessary to weigh out the small amounts of colorants required. At the opposite extreme are the large enclosed scales required by materials manufacturers for weighing all the ingredients for great batches of compound.



Premixing or blending

In any compounding or coloring operation, the properly weighed amounts of the various ingredients must first be mechanically blended before the mixture can be satisfactorily masticated. The material in the premixer may be wet or dry, depending on the type of plasticizer used. Some premixers, it will be noted, can handle either wet or dry mixtures, while others are suitable only for dry blends. Another major distinction may be made between mixers with internal moving elements to do the mixing and those in which the whole mixing chamber revolves.

Tumbling blenders: The tumbling blenders, which handle only dry mixes, are of many types, but in all of them the mixing is achieved by some type of turning action of the chamber containing the mix. One type is mounted on a horizontal axis and turns end-over-end vertically. In another, the steel drum is mounted on the machine base so that it rotates at an angle of about 30° from the vertical. This machine is one of those equipped with baffles to intensify the mixing action. In still another tumbling unit, the drum is mounted at an angle to the horizontal shaft and is balanced by another drum at the opposite end of the shaft.



None of the tumbler containers have moving elements, although

CARVER LAMINATING PRESS

. . . FOR PRODUCING

PLASTIC LAMINATED TAMPER-PROOF MOISTURE-PROOF Identification Cards and Badges Photographs, Important Papers . . . in sizes up to 9″x12″

Patented and Pats. Pending

Large material may be preserved by plastic laminating after being photostated or otherwise reduced.

PHOTOGRAPHS and records to be laminated are placed between two sheets of cellulose acetate or similar plastic, in stacks up to 6 layers, within the size of the platens. The layers are separated by polished plates. Each stack is accurately heated and cooled under controlled temperature and pressure.

The sheets are laminated and welded together with an impervious bond at the edges. Individual photos, cards of other laminated records are then trimmed on an ordinary photograph trimmer.

The press handles any of the standard or special plastic sheets suited to laminating.

No particular skill is required to produce up to 800 perfect laminations per 8 hr. day. The press is shipped ready for connection to standard electric outlet (110 volts A.C.) and cold water supply. No special wiring or plumbing required. 220 volts or D.C. if specified.

PROMPT SHIPMENT FROM STOCK

Carver Laminating Press (illustrated), Model 150, is available from stock. Polishing plates and blotters, 5″ x 6″ or 6″ x 6″, at slight additional cost. Cards, badges, and plastic materials may be purchased through regular suppliers.

some types do have curved baffles affixed to their internal walls to direct the material from one end of the barrel to the other as it is revolved.

A centrifugal-type mixer which was originally developed for use by food processors is suitable for blending batches of dry mixes. This machine has an enclosed motor which drives a directly-connected mixing rotor at high speed.

Ribbon blenders: Another type of premixer employing internal moving elements to effect the blending is a ribbon blender, which can be used with either wet or dry mixes. The mixing action is accomplished by several equally-spaced helical blades, rotating on a horizontal axis in an enclosed trough. The trough contains a top opening for feed purposes and a bottom port for discharge.

Plasticating equipment

After the initial premixing of the components of a molding compound in a blender, it is usually necessary that the mixture be worked into a soft (molten) state under heat and pressure. Among the intensive-type mixers suitable for plasticating are the Banbury, intermix, and spiral flow mixers, mill rolls, and extruding machines of various types.

Intensive internal mixers: These generally consist of a mixing chamber containing two revolving rotors. Clearance between the rotors and the wall of the chamber is small, assuring thorough mastication of the material between them. The material is charged into the chamber through a hopper. Generally, the mixer is equipped with a pressure ram which, when activated, forces the material into the rotors. Most mixers of this type are cored and jacketed for circulating a liquid heating medium.

Milling rolls: A set of milling rolls consists of two steel rolls, cored for the circulation of steam or other heating medium. The rolls are usually horizontal, parallel, and equidistant from the floor. They rotate slowly toward each other. The roll nearest the operator is known as the "mixing roll"; it turns slightly faster than

the other roll and is cooler. The space between the two rolls can be adjusted by the operator to exert the desired amount of pressure. Doctor blades attached to the rolls, or ordinary knives, can be used to cut the blanket of material adhering to the mixing roll so that it can be folded back for further mixing.

Multi-screw extruders: Twin-screw extruding machines are often used for compounding and coloring thermoplastic molding material. When used by injection molders, the material is generally extruded in the form of multiple rods or spaghetti which may be cut right at the face of the die, or may be conveyed through a cooling bath and thence into a pelletizer. When such a setup is used by extruders, however, it makes it possible to compound, color, and extrude into the desired section in a single operation. Two types of these multi-screw extruding machines are now being marketed in the U.S., one manufactured in this country and one in England.

In each machine, both worms participate in the kneading and heating operation, but in the American machine, the actual extrusion is effected by only one screw, the other one being shorter in length. In the British machine, the flights on the two screws are of the same pitch, permitting them to mesh, but in the American machine the worms do not mesh. The material is plasticated by the pressure and heat as it is forced against the heated cylinder wall by the revolving screw, and as it is advanced along the flights in the screw toward the front of the chamber. On both machines, the screws are machined with progressively finer flights, to handle the material as it becomes more thoroughly melted in the cylinder.

The size and shape of the cylinder chamber on each machine corresponds to the requirements of the screws. Thus, while both chambers are ∞ shaped at their feed end, the one in the American machine streamlines down into a conventional round shape at the discharge end, due to the fact that only one screw extends into the final section of the chamber. On

CARVER LABORATORY PRESS

Standard for Plastics Research Development and Control for More than Twenty Years

IN THOUSANDS of leading industrial firms, government and technological laboratories the Carver Laboratory Press is an indispensable aid in plastics research and development.

The Carver Laboratory Press, original in design, has long been accepted as standard for making quick, accurate small-scale tests; for development, research and instruction work; testing single cavity molds; preparation of samples, and even for small scale production. The Carver Press provides complete range of temperatures from room temperature to 400°F. Adjustable by thermo-switch to within plus or minus 2°F. Equipped with accurate 6" gauge, providing load readings up to 20,000 lbs. Low pressure gauges optional. Carver Standard Accessories include Electric or Steam Hot Plates; Electrically Heated and Water Cooled Hot Plates; Carver Test Cylinders; Swivel Bearing Plates; Cage Equipment, etc. The press and certain of the accessories are patented. Send for your free copy of our latest illustrated catalog, describing the Carver Press and some of its many applications.

the British machine, the ∞ shape persists throughout the chamber length.

Single-screw extruders: Some single-screw extruders, with worms especially designed to work the material thoroughly, are also used to compound and color thermoplastics.

Chopping, granulating, dicing

Theoretically, any crushing, grinding, or cutting equipment could be used for reducing thermoplastic compound to a size suitable for feeding into an injection machine or extruder hopper. In a specific case, the choice of cutting equipment will depend partly on the plasticating equipment that has been used and partly on the size and shape desired in the particles. Thus, compound coming in sheet-like form from mill rolls is usually broken mechanically, then fed first to a chopper where it is cut into large pieces, then to a granulator where the large pieces are converted into granules or powder. In contrast, rods of compound that come from an extruding machine are customarily cut by a pelletizer.

Choppers: The function of a chopping machine is to reduce continuous material, such as extrusions or sheets from mill rolls, to a size that can be conveniently handled by a granulator. The sturdy machine in which such rough, nonuniform cutting is accomplished is equipped with a series of rotating knives cutting against a bed knife. In fact, its operation is similar to that of a granulator.

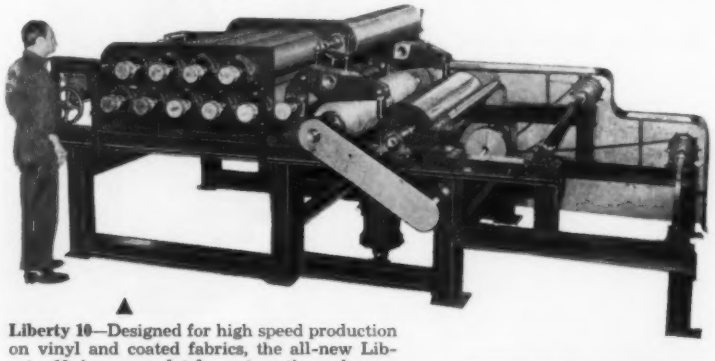
Granulators: The machines used for final granulation of the material are generally grinders or dicers. Scrap grinders may be used for granulation of virgin stock. Materials manufacturers require heavier machines, of greater capacity, though built on a similar principle. Some of the heaviest granulators may obviate the preliminary use of a chopper.

The cutting chamber of a typical granulator consists of a motor-driven rotor containing revolving tool-steel knives which cut against fixed stationary knives that are set at a slight angle in the cheek pieces. The size and number of both rotary

knives and stationary knives will vary with the size and requirements of the machine. However, there is always an equal number of knives in each of the two cheeks. The bottom of the cutting chamber consists of a perforated screen. The size of the holes will determine the maximum size of the particles leaving the machine, which may vary from 5/16 in. down to a fine powder.

Whether a pelletizer or a dicer is selected will depend largely on the form in which the plastic is to be fed to it. Thus, the multiple rods emerging from a compounding extruder are already of the desired diameter, so the pelletizer merely needs to be capable of performing one operation—cutting the rod into the desired lengths. When the stock is to be cut hot, the pelletizing device, called a fly-knife cutter, may be located grazingly close to the face of the extrusion die, which feeds directly into it. The die face acts as one "blade" of the "scissor."

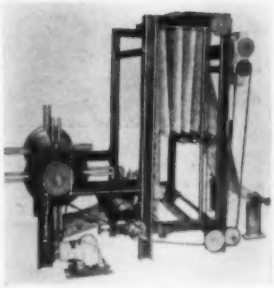
A typical fly-knife cutter consists of a single- or double-blade rotary cutter, mounted on a shaft that is turned by a small electric motor with variable-speed drive. In operation, as the cutter revolves, the blade or blades slice across the face of the die. Rate of extrusion, speed of revolution of pelletizer shaft, and number of blades will determine length of pellets.



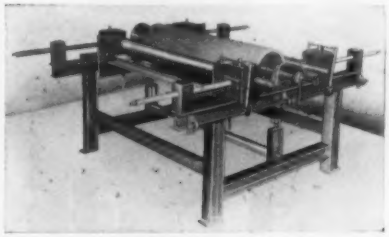
If the extruded rods or strips are to be cut cold, the pelletizer must be equipped with feed rolls to assure positive feed; constant rate is necessary if pellets are to be of equal lengths. The cutting blades revolve at right angles to the direction of feed.

When the stock to be pelletized comes to the machine either in the form of a sheet from milling rolls or wide strips from an extruder, the machine must be capable of cutting it both lengthwise and crosswise. Special dicing machines are made for this type of work; also available are slitting attachments for use on ordinary pelletizers. One machine, particularly suitable for cutting elastomeric materials but adaptable to rigid thermoplastics if they are fed warm, has a saw-tooth slitting roll instead of the feed roll

AT LOW COST
Liberty offers you high production film processing equipment

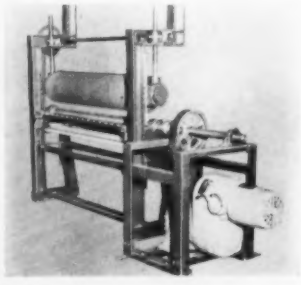


Here's a representative selection of Liberty machines. The *complete* Liberty line includes equipment for every step in film processing. And *every* Liberty unit gives you these advantages:



- **low initial cost**
- **rugged, designed-to-last construction**
- **easy operation**

▲ **Liberty 10**—Designed for high speed production on vinyl and coated fabrics, the all-new Liberty 10 is a completely automatic embosser. Ten electrically heated rollers permit speed up to 35 yds. per minute. And variable speed control assures proper rate of travel. Some basic design also available with 6 or 8 rollers.



Liberty Batcher—Speeds production by minimizing delay at take-off, and eliminates wrinkles. Provides operator with 70 feet of material to work with. Turret can be used on back of any web processing machine. Precision guides insure straight rewinds. ▶

◀ **Liberty Two Color Printer**—Handles material from 48" to 72" wide. Exact registration assured by three simple roller adjustments. Has same easily operated type controls as Liberty one color printer.

Liberty Single Color Printer—Handles material from 48" to 72" wide. Construction gives clear view of both doctor blade and cylinder at all times. Quick roller change-over and work-up possible without removing rollers. ▶

Write for your free copy of Liberty's new catalog, and get the full details on the complete line of printers, J-boxes, polishing machines and embossers.

Recent Development

A new principle in the design of ball mills cuts milling time by as much as a factor of 10. In the new mills, four individual pots are arranged on the periphery of a circle that revolves around a central drive while each pot also rotates simultaneously on its own driving spindle. The result is a greatly multiplied mixing action and the subjection of a greater amount of the pigment (for example) and the liquid to the grinding action of the balls or pebbles. *Kinetic Dispersion Corp., 95 Botsford Pl., Buffalo 16, N. Y.*

EQUIPMENT FOR PREFORMING

Equipment for preforming is divided into two general classifications. One is the type used by a compression or transfer molder for producing dense pills or preforms from powdered or granulated molding material, or from impregnated chopped fabric thermosetting compounds. The second classification is used only by the molder of reinforced plastics, and its function is to produce a preform of chopped glass fibers in the approximate shape of the desired end product, this preform to be sufficiently strong to withstand handling without falling apart.

This article will treat with the first type of equipment. Preform machines for reinforced plastics molding are discussed on p. 523. Preform presses are discussed in the section below.

The chief function of a preform press is to compact loose plastic material into a dense shape that can be handled easily during preheating and mold loading operations. Preforms also assure uniform mold charges.

In addition to preforming, high-

speed cold molding can be accomplished on the preforming type of press. A floating head press is especially adaptable for this specialized operation, using a set of embossed dies.

Types of presses

There are two methods of classifying preform presses. One distinction is on the basis of single-stroke or rotary design, the other on the basis of mechanical or hydraulic operation. All types have variable-speed drives and a means for manually adjusting the weight and density of the preforms. On some of the machines, these adjustments can be made while the preform press is in operation.

Single-stroke presses may be operated by mechanical or hydraulic means or by a combination of the two. The mechanical type, which is the more common, may be actuated by a cam, toggle, crank, or eccentric mechanism.

The hydraulic type of press is less commonly used; a single-acting press of this type may be indicated for handling materials that cannot be fed automatically.

In general, in the standard automatic, mechanical single-stroke press, a volumetrically determined charge is fed into a stationary die cavity by a reciprocating or oscillating feed shoe. The hydraulic single-stroke press, on the other hand, is semi-automatic and the operator loads a measured charge into the die before the start of each pressing cycle.

To make preforms of a given contour on a single-stroke press, only a single die set is required. This will include a die block containing one or more cavities, and a corresponding number of upper and lower punch sets. A single-stroke press will deliver up to 60 preforms per minute. Although multiple punches can be used on this type of press, they are not in general use because of high initial cost.

Standard single-stroke presses apply the compacting load from one direction only. However, some special models compact from both directions, either by direct motion of both the opposing sets of punches, or by the use

molding, embossing, polishing, laminating . . .

PLASTIC

R. D. Wood Hydraulic Presses are designed to meet the many exacting demands of modern plastic product manufacturing.

Accurate and uniform heat-pressure distribution of R. D. Wood Presses provides high product uniformity under mass production conditions. Full production speeds and economies are assured by automatic and semi-automatic pressure controls, blow down, heating and cooling units; central and self-contained hydraulic systems; special platen arrangements and many other features.

R. D. Wood Presses are available in a wide range of models and capacities for many production requirements.

Before you buy, consult R. D. Wood Company. Write today for details of our full line of Hydraulic Presses and Equipment.

TEMPERATURE CONTROL

keeps plastics production flowing freely

Call in a Powers engineer and you'll have fewer production headaches on your high-volume molding. He'll gladly help you in planning, and in specification of Powers temperature control equipment. He'll furnish service and maintenance instructions for your men — expert installation, too, if you wish. Prompt delivery from local stock. Seventy offices in the U. S. and Canada. Phone your local Powers office or write us today for a copy of "Temperature Control Reference Manual—Plastics Industry."

Final adjustments during installation of Powers Series 100 Indicating Controller (A) with remote sensing bulb, and Flowrite Valve (B) at Bell & Howell Co., Chicago. This equipment provides close control and proof-at-a-glance of compression molding die temperature. Result: more perfect parts per day—fewer rejects.

THE POWERS REGULATOR CO.
Skokie 34, Ill.

POWERS
PROCESS CONTROL

of a floating die, which is forced against the stationary set of punches by the motion of the opposing set of punches.

Other special models use hydraulic cushions to secure a slight dwell during the compacting operation. Such a dwell allows more time for the escape of air entrapped in the powder, and also permits the material to flow easily through complicated die areas.

Single-stroke presses are available in capacities of up to 200 tons; the largest size is capable of making preforms 28 sq. in. in area and weighing as much as 2½ lb. each at a speed of 45 or 50 per minute. A 75-ton press has satisfactorily produced ⅛-in. diameter preforms at the rate of 10,000 per min. in a 160-cavity die.

The single-stroke presses are particularly well-suited to the needs of molders who have a wide variety of preform requirements, because large and small preforms of various contours can be made with equal facility on the same machine, and because die changes can be accomplished with a minimum of downtime.

Rotary presses

Rotary presses are mechanically operated. They employ a number of die sets, mounted on rotating members. The material is compressed from both top and bottom, as the die cavity block and both the upper and lower punches of the die set move simultaneously between revolving wheels. Ejection of the preforms is accomplished by cam actuation of the lower punches.

As in the case of single-stroke presses, charges for the rotary presses are volumetrically determined. However, in the case of the rotary presses, the dies do not remain stationary for filling as they do on single-stroke presses. Instead, the cavity is filled by moving it underneath a stationary material feeder.

Even with single-cavity die sets, production on a rotary is fairly high. In a single revolution of the die table, one or two pills are produced per die set, and there may be as many as 33 of these die sets on the die table.

Rotary presses are available in

capacities up to 100 tons. The largest machine is capable of making 60 six-in.-sq. preforms per minute. Special presses designed to accommodate multiple-cavity die sets have turned out as many as 4000 preforms per minute.

Changing the die sets on a rotary press requires considerably more time than on a single-stroke press; however, molders find the rotary type of press to be economical for long production runs.

For the molder to select the particular model and size of press that will best serve his needs he must have a clear understanding of three interdependent groups of factors: 1) *production requirements;* 2) *material characteristics;* and 3) *press limitations.*

Production requirements

When the molder customarily produces a variety of end products in relatively small quantities, he will usually find a single-stroke press best-suited to his needs, since such a press can accommodate a great variety of sizes of preforms, and, in addition only one die per size is required, whereas for a rotary unit up to 33 die sets per different size and shape would be needed. The molder who specializes in volume production of parts that require preforms of the same size and shape, such as a mass producer of buttons, collapsible tube caps, and closures of other types, will require a rotary preformer. The higher cost of the die set tooling is justified in this case since it is amortized over many millions of preforms. Most custom molders find that they require both the rotary and single-stroke types of preformers, because of the diversity of products they manufacture.

Material characteristics

Uniformity of density, thickness, and weight of preforms will depend partly upon the uniformity with which the material is fed into the preform die cavity. This, in turn, depends partly upon the granulation, flow properties, and bulk factor of the plastic material being fed. Materials of different feed characteristics may demand the use of different types of presses.

Granulation: The granulation

CUSTOM DESIGNED & MANUFACTURED
CONTINUOUS PROCESS SYSTEMS

SURFACE COATING SYSTEMS
. . . . for fabrics, paper and films
High-production machines are available for the application of plastisols, hydrosols, organosols and other surface coatings to continuous web materials.

IMPREGNATING SYSTEMS
. . . . for fabrics and paper
Varnishes, latices, rubber solutions, etc., are saturated into continuous web materials for the manufacture of electrical tapes, conveyor belting, pressure-tight fabrics and the like.

ROLL AND KNIFE COATING MACHINES
Reverse roll, rotogravure, knife-over-roll, floating single- and double-knife coaters, or a combination of several machine types are furnished for installation in the customer's coating line.

EMBOSSING & LAMINATING SYSTEMS
Low- to high-pressure roll embosser or laminating units are available in single and dual head designs.

FIBER ORIENTING SYSTEMS
Complete orienting systems are available to improve tensile strength and reduce elongation in a variety of synthetic fibers.

OMNI PRODUCTS CORPORATION, Export Distributors, New York, N.Y.

of general-purpose materials do not usually raise any feed problem. The occasional slight segregation of particles by size within the cavity is usually not serious enough to warrant the use of special devices to control it. But when the material is in the form of a fine powder or contains a high percentage of fines, air entrapment may create a problem. This can be alleviated to some extent by increasing the clearance between die and punch or applying a vacuum to the die cavity. The slower-acting hydraulic type of press will allow more time for air escape than the mechanical type, if other performance considerations do not outweigh this particular advantage.

Bulk factor: The bulk factor of the material to be preformed is a very important determinant on the choice of the particular model of preforming press, for it influences both the type of feed arrangement required and the depth of fill necessary on the press for efficient performance.

On the basis of bulk factor alone, a quick choice may be made between standard machines and those designed to handle high bulk factor materials. Most standard machines are intended to handle general-purpose materials with bulk factors as high as three to one. When equipped with special rotary feeding devices, they can be used with materials having bulk factors as high as six to one. However, when the bulk factor is higher than that, special presses must be used. On the other hand, the type of machine designed to handle high bulk factor materials would be uneconomical for use with ordinary materials because of the additional expense factors which are involved.

The bulk factor not only affects the type of feed required on the press, but also may, in combination with preform thickness requirements, determine the depth of fill required on the press. For example, if a material with a bulk factor of two to one is to be used, and a 1-in.-thick preform be made, a press with a 2-in. maximum depth of fill can be used. However, if the bulk factor

of the material is four to one, this preforming machine will not be satisfactory, as the maximum preform thickness would be ½ inch. In this case, to produce a 1-in.-thick preform from the same material, a press with at least a 4-in. maximum depth of fill is needed.

Press limitations

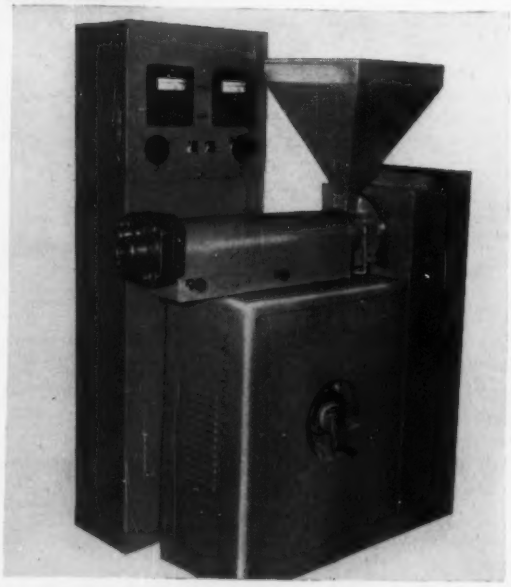
Static pressure: The static limit of a machine is the amount of applied force which the machine will withstand without permanent deformation or damage.

Power limitation: The power limitation is a little more difficult to understand, because it depends upon the primary driving motor of the press, the inertia of the moving parts, and the speed of operation. Basically, it can be explained thus: In preforming, a definite expenditure of energy in the form of work is required to compact and eject a pill. This energy requirement varies with the depth of fill, the configuration of the die, the type of material used, and its condition. In addition to the work required to make the pill, an added amount of energy is used to deflect the stress portions of the machine and to overcome friction during the pelleting operation. The total energy must be supplied by the driving motor; otherwise, a degenerate cycle exists.

Die area: The die area limits the size of the die or the number of cavities that can be placed in a single die in the press.

Core rod placement: The limitation for the installation of core rods is a point not often considered in the selection of preform equipment. Yet it is a decided advantage to be able to produce core preforms for use in compression molding of certain types of pieces requiring many complicated die cavities.

Feed arrangements: The gravity-feed hoppers with which most standard machines are equipped provide satisfactorily uniform feed with most general-purpose materials. However, special auxiliary mechanisms, or even special presses, may be required with the high bulk factor materials.



Vibrators are sometimes used

to facilitate feeding of material that will not feed properly from standard gravity-type hoppers. A rotary type of brush feed mechanism is also available, for handling fluffy medium-impact materials having bulk factors of between 3:1 and 6:1. For high-impact materials containing rag or canvas filler, and having bulk factors as high as 16 to one, it is necessary that each preform charge be weighed, since no bulk measurement system will produce preforms which are sufficiently accurate in uniformity.

EQUIPMENT FOR HEAT-SEALING

Primary function of heat-sealing equipment is to supply sufficient heat and pressure to bond two or more heat-sealable surfaces together. Heat-sealable materials may be classed as those materials which melt or become fusible at temperatures generally ranging between 150 and 350° F. When two pieces of material of this type are pressed together and the contacting surfaces raised to the temperature at which the material melts, a weld can be made.

Heat-sealing equipment for thermoplastics materials are of two general types—one type uses electrical resistance elements to heat jaws, rollers, or metal bands; the other uses a high-frequency generator for the purpose of heating the material.

One of the recently developed processes makes possible the production of multi-colored rims and edges for three-dimensional appliques in a single heat-sealing operation. To accomplish this, a special die, built to the design of the required applique, not only heat-seals the applique, but also provides a tear-seal to the same design. Thus, after the applique has been bonded to the film being decorated, the operator merely strips the excess material, which tears smoothly and uniformly at the edges of the applique.

Resistance heat-sealers

Heat-sealing accomplished by means of electrical resistance elements requires a cooling of the seal under pressure to insure the bond strength for most plastics films.

Electrical resistance heat-sealers are of two general classes: the jaw type and the rotary sealer. The simplest is the jaw type in which two heated metal bars or platens are brought together by a mechanism operated either by hand or motor.

There are two types of rotary sealers. In one type, sealing is effected by passing the material between two heated motor-driven rolls. The second makes use of two thin endless metal bands which carry the material through both the heating and cooling zones while continuously applying pressure to the film. By permitting the accurate control of temperature, pressure, and time, the latter machines may be used for heat-sealing oriented films and those with a low heat dissipation factor, as well as the regular thermoplastics.

Both rotary- and jaw-type sealers usually have sealing members made of brass. Steel members are sometimes used because of better wearing qualities, but since the thermal conductivity of steel is low, this material is recommended only for automatic machines which handle films at fixed speeds. The fixed speed permits the adjustment of heat input to heat output. For semi-automatic machines, which are those guided by operators, attempts are made to feed the same number of units each minute since variations in feeding speeds induce variations in temperatures. Provisions for making pressure adjustments are necessary for both types.

High-frequency sealers

Electronic or high-frequency heat-sealing takes advantage of the electrical characteristics of many plastics materials. In this

RECENT DEVELOPMENTS

A heat-sealer that closely resembles an office desk combines a dielectric heating generator with a clam-type press. Areas up to 12 sq. in. and straight seals as long as 20 in. (45 in. on special order) may be sealed in one cycle. Cycles are automatically timed and the rated output may be either 2 or 3 kw. *Erdco Engineering Corp., Addison, Ill.*

A semi-automatic heat-sealer that seals unsupported plastics films (including polyethylene) and plastics-coated sheeting is the Model 54UL. It uses an electrically heated platen and a clamping pad faced with fibrous-glass-reinforced Teflon. *Product Packaging Engineering, 5747 Marilyn Ave., Culver City, Calif.*

Combining several pieces of equipment, a new process for fabricating plastic curtains is capable of turning out 1800 to 2000 units per day. A rotary sealer, drawing sheet from continuous rolls in widths up to 72 in., first side-hems the material, after which it is re-rolled. An 80-in. "thruway" press then attaches a clear, heavy-gage vinyl header, forms 12 grommets with tear centers, and bottom-hems the curtain. *Mayflower Electronic Devices, Inc., Little Ferry, N. J.*

Electronic sealers with outputs of 0.5, 1, 3, and 5 kw. can handle a wide variety of seal patterns. The top of the generator housing is designed to be used as a work table, and the controls and indicating meters are all set into a convenient sloping panel at the rear edge of the table. *Raybond Electronics Inc., 66 Needham St., Newton Highlands 61, Mass.*

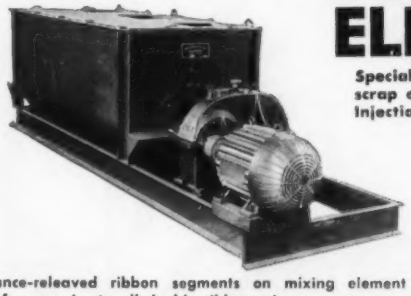
A heat-sealing machine (U. S. Pat. No. 2,747,646) combines radiant heating with dielectric heating to make possible two- or three-color tear-sealing of appliqués on vinyl sheet. Under certain conditions more than three colors can be used. General characteristics are: Power input: 40 amp. at 220 v., single phase, RF output: 3 kw. *Cosmos Electronic Machine Corp., 656 Broadway, New York 12, N. Y.*

Recent Developments were excerpted by the editors from MODERN PLASTICS, Oct. 1956 through July 1957.

method, the heat for sealing is generated inside the material by the passage of high-frequency electric currents through it. Since only the inner surfaces of the film soften, no cooling zone is required, so that cooling and bonding are almost instantaneous.

There are three basic parts to an electronic sealer: the oscillator or high-frequency generator; the mechanism for applying pressure, such as a press or a frame for mounting rollers; and the electrodes. The high-frequency generator is in principle a radio transmitter with its output side connected to the electrodes of the sealer instead of to a transmitting antenna. Most oscillators are tuned to 27.12 ± 0.16 mc., one of the three frequencies assigned by the Federal Communications Commission, although well-shielded oscillators may operate at any frequency.

Prefabricated shielded rooms of various sizes have recently been made available in kit form for shielding oscillators which do not operate at the required FCC frequency. These rooms have copper or bronze screens and leakproof doors and air intakes.



In bar or "one-shot" sealing the electrodes are shaped to the profile desired in the bond. In some instances the electrodes may be machined dies with one placed in the upper and one in the lower section of the press. In one widely used setup, a single set of formed electrodes in the upper portion of the press seals at all points of pressure against a flat plate electrode in the lower portion of the press. The problems of special dies are eliminated in some machines by the use of a brass strip which can be adjusted to produce any shape of seal.

In continuous sealers, the electrodes may be machine-driven rollers which not only transmit the high-frequency energy but also act as a feed for the film passing between them. While some continuous sealers are large units, most are of the sewing-machine type. Another variation of the continuous sewing-machine-type sealer makes use of very small bar electrodes. The rapid clamp action of these mechanically operated bars pulls mate-

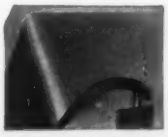
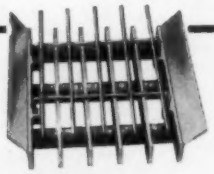
Improved Pre-Plasticizing



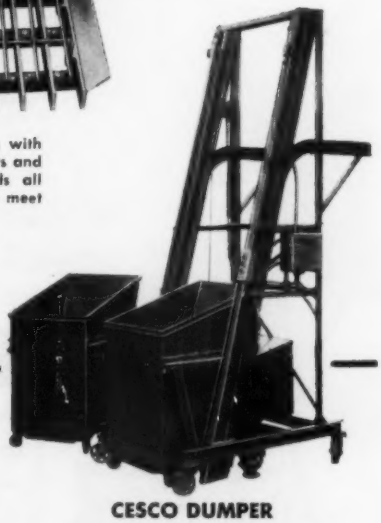
BAILEY BLENDER ELEMENT



Specially developed for mixing vinyl scrap or virgin plastics.
Injection Molding
Extruding
Calendering

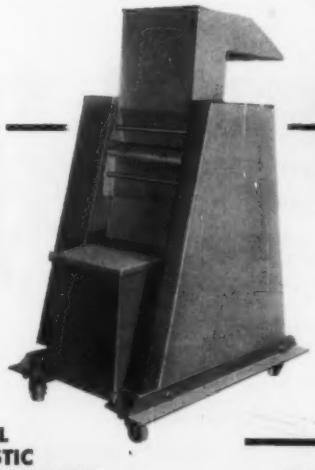
Clearance-releaved ribbon segments on mixing element prove far superior to all double ribbon mixers.

- Increases blending efficiency, makes a *better* mix *quicker*.
- More thorough emptying of blender—faster cleanup.
- Reduces maintenance costs.



ROUNDED CORNERS
for quicker, more complete cleaning—no contamination between batches.

MAGNETIC GRATE SEPARATORS



Prevent Costly Damage

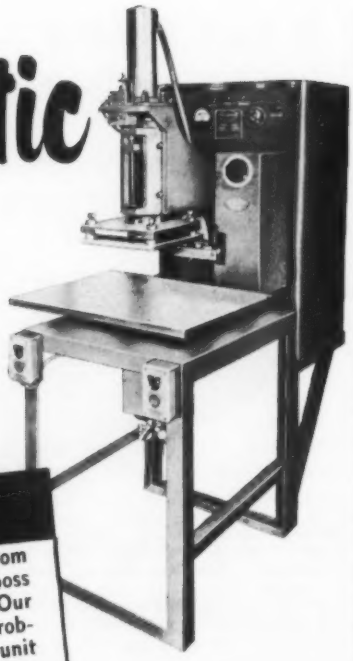
Highly saturated Alinico No. 6 magnets with steel intervening bars for extruder hoppers and granulator discharge. Attracts and holds all ferrous objects. Stock or special sizes to meet every requirement.

CESCO DUMPER

Portable Banbury or extruder loader with quick-cleaning, stainless steel batch buggies. Ideal for loading pre-blended materials or materials of different colors. Extra buggies available —dumper can be used with bags, barrels and drums as well.

IDEAL PLASTIC GRANULATOR

Grinds polyethylene and vinyl without fluffing—no fly backs or leakage. Rotary and stationary knife combinations made of special high speed tool steel wear longer with minimum resharpening. Extra large removable bin and cover. Ten sturdy, all-steel models to choose from—all adaptable to specific purposes: air take-off systems, roll feeds, wider throat openings.



Write for complete details on these and other mixing, grinding, elevator, and sifting equipment.

rials forward at each stroke. The forward movement of the material results in an overlap at each point of weld. It is possible to bond practically any desired seam by use of the sewing-machine-type sealer. Needle trade operators can also rapidly learn to use this type.

EQUIPMENT FOR REINFORCED PLASTICS

Because of the different methods used to produce molded reinforced plastics parts, the equipment that is required is necessarily varied.

For simple bag molded parts, the equipment need include only a mold, a flexible bag, a vacuum pump, and an oven or a bank of infra-red lamps. However, when producing large parts in matched metal molds, the required equipment will include many complex items such as air or hydraulic presses having a large platen area and adjustable daylight as well as long and fast ram travel; timers and controls; special machines for making preforms from chopped fibrous glass rovings; curing ovens; and materials handling equipment. The latter conveys preforms to the oven and then to the press as well as transports the molded parts to finishing and shipping stations.

For high-speed production of noncontinuous reinforced plastics sheet, the major items include a coating device equipped with squeeze rolls or some other resin metering device, numerous highly polished steel caul plates, a multiplaten press, and a large shear for trimming the edges after molding.

Continuous sheet may be produced with paper, fibrous glass, or other suitable reinforcement, using a "nonpressure" curing resin as the binder. By this method, one or more rolls of web are mounted so that they can be fed through an impregnating tank or under a sprinkler-type of resin applicator, and then to a set of combining rolls which also serve to squeeze out the excess resin. These rolls are fitted with end gates which keep excess resin from flowing out at the edges. Such gates are adjustable for width of web. As the individual

webs combine, "carrier" webs of cellophane or coated paper fed from nearby let-off rolls join the assembly as top and bottom surface coverings. Carrier webs are usually 4 to 6 in. wider than the laminate.

The feed of the carrier web is controlled by brakes and side adjustments. The curing section is usually a textile tenter frame, or a modification thereof, which carries the laminate through the ovens. Ovens are 50 to 100 ft. long and are zoned into three to five sections where preheating, curing, and after-heating take place.

Wind-up rolls

Carrier sheet removal is accomplished by wind-up rolls, suitably clutched. The cured laminate is then trimmed at the sides by saws or rotary shears. Cut-off into desired sheet length is done with electric sheet-metal shear equipment. The shear must be properly maintained; a poorly adjusted or dull shear will cause delamination.

Sanding the back of the laminate is necessary in order to provide good adhesion. Special sanders are available which perform this operation uniformly and quickly.

For all types of molding, except that in which pre-impregnated stock is used, it is necessary to have weighing and mixing equipment for the preparation of resin.

All reinforced plastics parts require grinders or sanders for flash removal and many items require edges smoothed by buffing.

For a complete discussion of the various types of preforming equipment which are available, see p. 523.

References

For further information on reinforced plastics materials, see chapters listed on p. 506, as well as the Low-Pressure Laminating Resins Chart. Also consult the Subject Index, and the Directory Index, p. 1018.

Gardsman TUBELESS* TEMPERATURE-CONTROLLERS

Model JP Series
PROPORTIONING Controllers

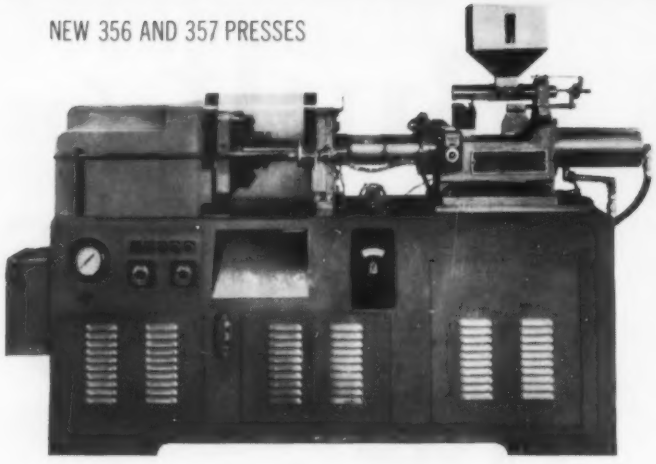
This time-proved unit is widely used for closer control than the basic On-Off system permits. JP *anticipates* temperature changes, tends to stabilize the system to desired temperature, makes new harder-to-mold materials a simple production job.

Model JPT Series
3-POSITION Proportioning Controllers

Designed especially for plastic extruding and injection molding machines, to control heating of barrel or cylinder, and cooling with either air or water. Ideal for high-friction materials like Rigid Vinyl. Provides Model JP Proportioning Control of heaters *plus* automatic control of cooling cycle *only* in case of overshoot caused by heat of friction or temporary shut down. Avoids heat-waste and decomposition of plastic materials.

Model JS Series
STEPLESS Controllers

Closest practicable control, virtually eliminates temperature variable. Constantly modulates input to demand. Prolongs heater life by reducing thermal shock. No tubes, no relays. Multi-load units, adjustable control-band width, manual reset. Simplest operation: one knob.



**Minimum maintenance. No need for "tuning" to suit tube-ageing. Reliable — Guaranteed — AND these Gardsman Controllers save on original cost! Specify model series in writing for data.*

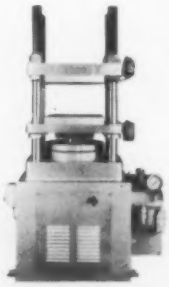
HYDRAULIC PRESSES

NEW 356 AND 357 PRESSES

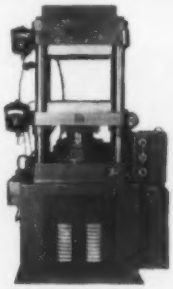
WITH MORE *Plus* FEATURES!

CAPACITY: 2¾ oz. at single stroke of plunger; up to 5 oz. with pre-packing



HIGH SPEED: Plasticizes up to 30 lbs. of material per hour

VOLUMETRIC FEEDER: For accurate material delivery to plunger



ADDITIONAL FEATURES: Up to 12" x 12" mold; heavy duty toggle clamp; up to 15 oz. heating chamber capacity; chrome plated cylinder; push button controls; thermostatic heating cylinder control; movable die plate for purging to change material or color.

Versatile presses with power plants designed to develop injection pressures up to 20,000 lbs. PSI. Will handle almost any molding material. Low initial cost, combined with high capacity, automatic operation and low operating costs, rate the 356 series as the "Best Buy" in modern injection equipment. Increased production lowers unit costs and that means higher profits. Model 356 rated at 20,000 lbs. PSI; Model 356A at 10,000 lbs. PSI.

MOLDING MAGIC!

MOLD UP TO 1620 BIG PROFIT ITEMS PER HOUR . . . LIKE MAGIC

PRESTO . . . PRODUCTION and PROFITS!

Yes, it seems like magic the way this machine converts raw material into finished goods, in one continuous operation. With only one man at the controls, polyvinyl chloride plastisols are automatically dispensed and rotationally molded to shape, completely controlled by the automatic features of the machine. The operator need not be a technician, because all the plastisols are scientifically prepared, using all the technological advances made by the nation's foremost companies. Now, any hollow article can be molded from polyvinyl chloride plastisols, thus creating countless new product possibilities. With a high hourly production and a low hourly cost, it naturally follows that units produced on this machine are BIG PROFIT items.

LET US SHOW YOU HOW TO DO IT!

We want to demonstrate our "magic" to you. Visit our plant and let us mold YOUR PRODUCTS, right before YOUR EYES . . . like "magic".

Write or call for detailed data or an appointment.

NOW . . . even BIGGER!

Machines are now available with a 15", 25" and 75" molding area, able to mold items *eight times larger* than previously thought possible. Items such as the unicorn, shown here. Imagine, it's automatically molded, in one operation!

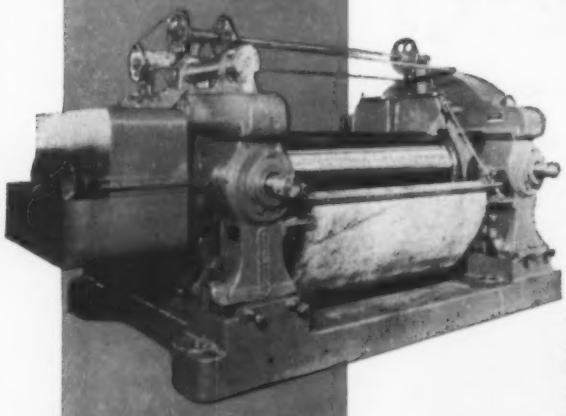
CALENDERS

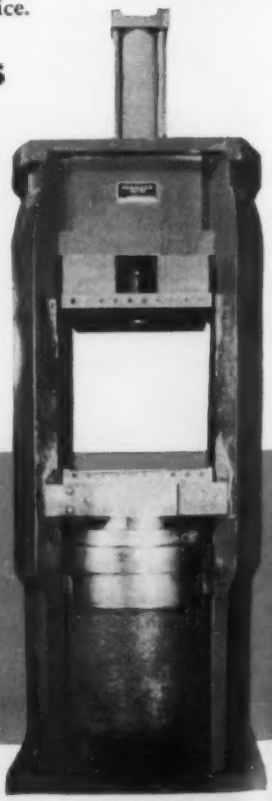


We make all types and sizes of Calenders, precision designed for extremely close tolerances to meet the most exacting requirements in the production of plastics film or the coating of fabrics with rubber or plastics. The unit shown is an ADAMSON UNITED 32" x 92", 4-Roll Plastics Calender geared to produce 72" wide vinyl film, 2 mils. or less in thickness at speeds to 150 YPM.

RUBBER and PLASTICS

... designed and built by...

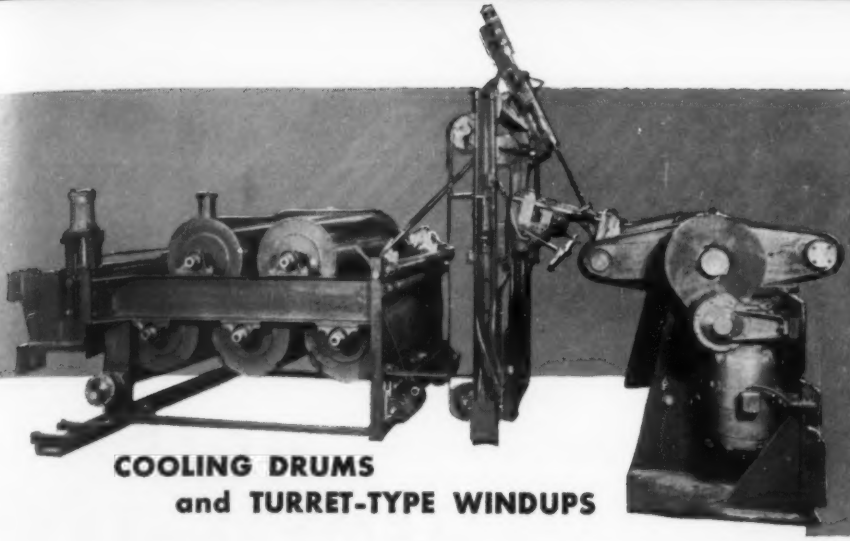
We engineer and build all types of individual production units and complete electronically controlled trains with all accessories for every Rubber or Plastics processing requirement. Our highly specialized engineering and production facilities plus the combined research and technical abilities of United Engineering and Foundry Company, and the manufacturing capacity of eight modern plants, are at your service.



MILLS

An 84" Individual Mill equipped with a mixing apron. ADAMSON UNITED Mills may be had in all sizes from 6" x 16" to 28" x 84", driven individually; in pairs with right angle reducer between the units, or grouped on a line shaft with reducer at one end of the shaft. Apron, as shown, can be installed on any type of existing mill.

PRESSES



We build all types of presses for the rubber, plastics and plywood industries. Shown is a new 24" ADAMSON UNITED BARREL TYPE PRESS with transfer cylinder. This new press, an exclusive ADAMSON UNITED development, exerts up to 76% more platen pressure than conventional types without change in present hydraulic lines. Stock is transferred into the mold cavities through sprues which reduces cure time and flash trimming to a minimum. Sizes range from 12" through 32" with larger sizes available to specification.

AUTOCLAVES or VULCANIZERS

Built to specific requirements from 18 inches to 15 feet in diameter, any length, vertical or horizontal to withstand internal pressures as high as 1000 lbs.-per-square-inch. The Pot Heater shown is a vertical, cylinder-operated breech-door type.

COOLING DRUMS
and TURRET-TYPE WINDUPS

This is a standard type of accessory equipment arrangement for plastics film. It consists of embossing equipment; cooling unit; slitting devices; compensator stand and automatic turret windup. The turret windup stand is a center-drive-type with automatic indexing equipment, yardage counter, and adjustable tension control. We design and build entire calendering process systems including all accessory equipment.

ROTOCURE*

A new machine for the continuous curing of all flat rubber or plastics articles with smooth or designed surfaces. Rotocure increases production through continuous operation without opening, cooling, reheating and closing. It eliminates overcuring or undercuring of the over-lap areas occurring on conventional presses. Roll and belt changes, incident to design requirements, can be made on this new 60" x 80" Rotocure in one-tenth the time formerly required.

* Rotocure is a patented development of Boston Woven Hose and Rubber Co. and is built by Adamson United Co. under a licensing arrangement.

THERMOLATOR

REG. U.S. PAT. OFF.

The Best Is Your Best Buy!

(a)

MOLD TEMPERATURE CONTROL

Is the original system of controlling mold faces at optimum temperatures by high velocity circulation of water, at precisely controlled temperature, through the channels in the mold.

Pays Off in . . .

Increased Production Speeds—Many users say 100% increase over over use of cold water in molds.

Lower Rejects—Molders experience marked reductions in scrap, with important savings as a result.

Improved Casting Quality—Surface quality improves; strains reduced; sinks minimized; dimensional accuracy improved.

Start Up and Trial Shortened—Because molds can be brought quickly to optimum temperatures, and held precisely, start up and trial times are all reduced.

(b)

(c)

Models For Every Need

(a) Model "H" Automatic THERMOLATOR—Control panel shown. For location alongside existing press control panel. Pyrometer Scales and Pilot Lights provide instant check.

(b) Model "H" Automatic THERMOLATOR with Controls Integrated in Master Control Panel—All press and mold controls in central location, built in master panel by instrument manufacturer.

(c) Model "C"—The original THERMOLATOR with semi-automatic controls. Holds mold temperatures in range of ½°-F. up to 250° or 600°.

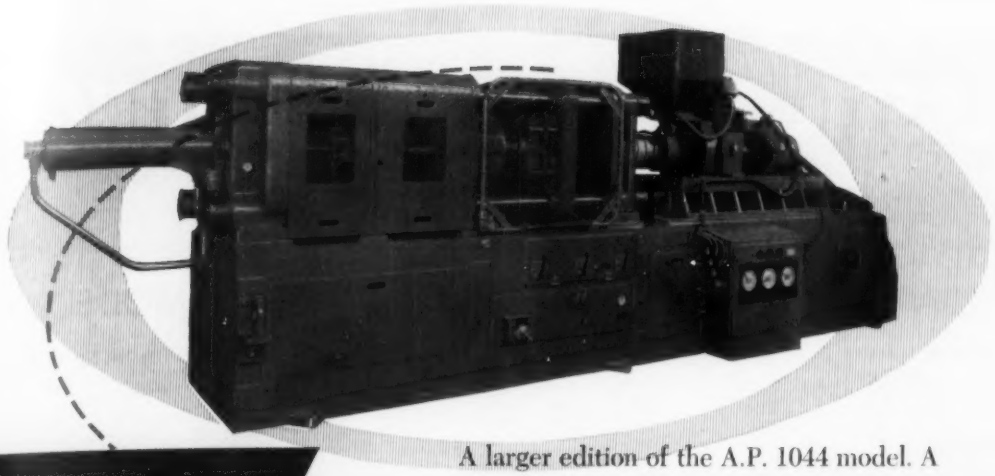
INJECTION MOULDING MACHINE

WITH THE BUILT-IN REPUTATION

A 1957 addition to the world famous Windsor range



all these outstanding features are in the latest Windsor model

120 cubic inch capacity (equal to 90 ounces of Cellulose Acetate). "Autoplas" multi-screw pre-plasticising and injection unit, hydraulically retractable. Vickers-Detroit type control gear with Vickers Armstrongs' delivery pumps. Power unit incorporates 50 h.p. motor and pumps. Mould locking force of 750 tons. Main locking ram, cylinder and the moving platen move easily as a unit to take moulds of varying thicknesses. Separate heating control cabinet.

Fully illustrated literature of the complete range of Windsor machines is available on request.

A NEW
COST REDUCING FEATURE

"AUTOMATION in PLASTICS"

NOW POSSIBLE WITH THE *Logan*

HYDRAULIC PREFORMER

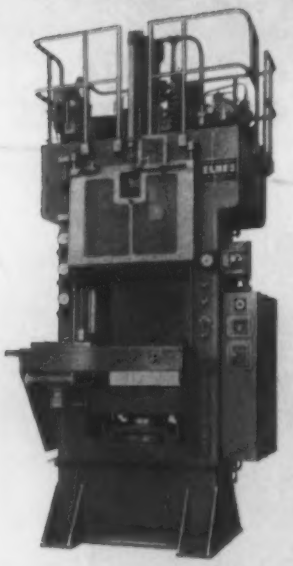
FOR HIGH BULK MATERIALS

Rag or flock filled, melamine "Fines" or general purpose materials can be preformed automatically. Large die area permits production of maximum size preforms. Multiple cavities can be used for smaller preforms. Processing with high bulk materials in your plant becomes automatic if you own a Logan Preformer.

If You Need a Hydraulic Press,

Check LOGAN Before You Buy

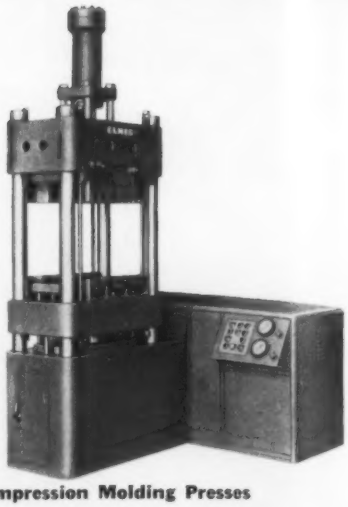
Automatic molding with Logan horizontal transfer machines and using preforms of high-bulk-factor type materials is the new way to reduce costs. Logan also has a complete line of semi-automatic molding custom engineered presses for compression and transfer use. Their exclusive features will appeal to you.



You will find it profitable to discuss your production problem with a Logan Engineer.

LOGAN HYDRAULICS, INC.

A SUBSIDIARY OF LOGAN ENGINEERING CO.



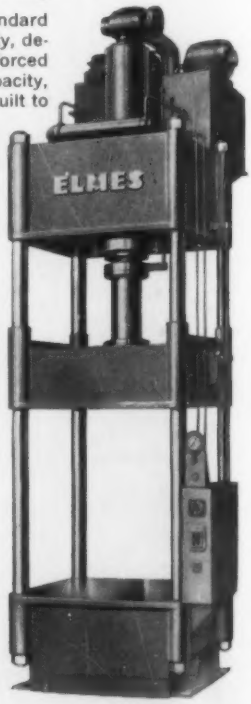
4901 WEST LAWRENCE AVENUE • CHICAGO 30, ILLINOIS

For press performance at TOP PROFITS...

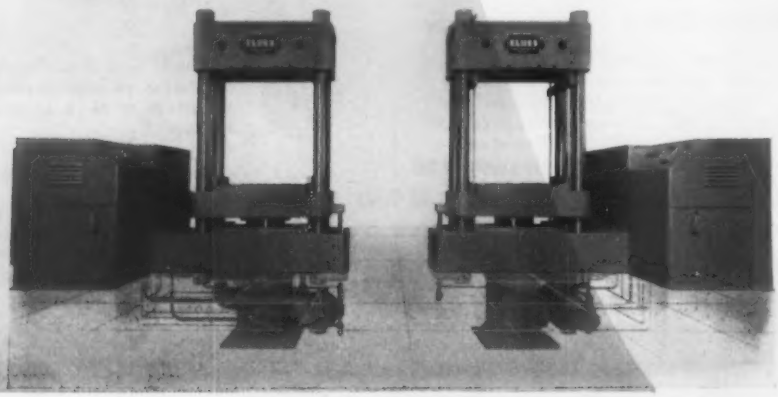
Are Your Requirements Special?

There are times when a standard press won't do. An example is the Elmes custom-built 200-ton Transfer Molding Press shown at left. If your requirements are special, and whether they call for a press newly designed throughout or just modification of an existing design, Elmes background, facilities, and foresight can save you many dollars—assure you press performance at its best.

Transfer and Compression Molding Presses



The standard design molding press illustrated above is typical of the Elmes full range of sizes for fast, accurate, economical production. Convenient pushbutton panel; pushbutton pneumatic reset of lower knockout; automatic position slow-down; extra large die space; many other features. Compression presses from 50 to 1000 tons. These presses are adaptable to practically any kind of molding problem with no changes other than dies and control settings.

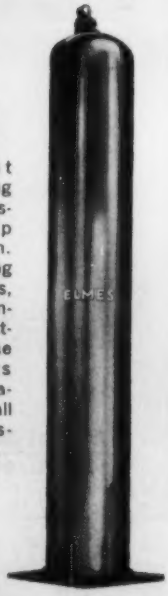


Installation of "Twin" Compression Molding Presses

The twin molding presses illustrated below make a compact installation, enabling one man to operate both presses. The presses are identical except that one is equipped with left-hand and one with right-hand controls and top knockouts. In addition to greatly improved ease of operation, time-saving convenience in servicing also has been achieved in the installation. Both presses are four-column moving-up type. Each press has a capacity of 300 tons. Here is an example of a typical adaptation of a standard Elmes Press design to provide equipment exactly suited to the job.

Presses for Reinforced Plastics Molding

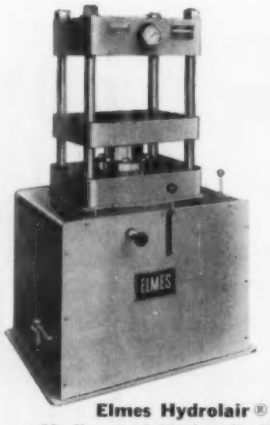
Elmes offers a complete line of standard presses from 50 to 600-tons capacity, designed specifically for molding reinforced plastics. Standard models of larger capacity, or custom-designed models, can be built to suit special requirements. Fully pushbutton controlled. Rapid advance, automatic slow-down, pressing speed adjustable to practically 0" per minute. Stripping speed can be controlled by the operator from maximum to approximately 0" per minute. Timer can be pre-set for cure cycle desired. Return stroke is adjustable to any determined length.



ELMES *"Job-Fitted"* HYDRAULIC PRESSES

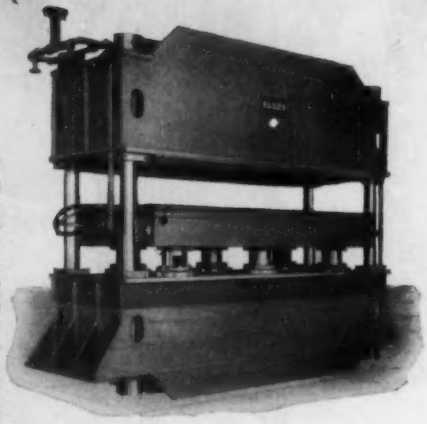
Elmes® plastics molding equipment, backed by over a solid century of engineering experience, is convenient and simple to use . . . fast, flexible, and economical to operate. And most important—whether it is a standard Elmes design or a unit custom-built to meet special needs, an Elmes Press is always "job-fitted" to the customer's production requirements. For all kinds of pressure applications in the plastics field you can count on Elmes for performance that turns cost figures into profit figures.

Elmes offers a complete line of *standard* equipment, including compression and transfer presses; Hydrolairs®—power presses requiring neither pumps nor motors; small-production, laminating, and laboratory presses; and Elmes pump-accumulator systems for group press operations. Or if your requirements call for *special* designs, Elmes engineers can develop equipment to suit your particular needs.



For detailed information on Elmes plastics molding equipment, contact your Elmes Distributor, or write to us direct.

Air-Ballasted Accumulators



Today's best means for storing liquid under pressure for group press operation. No internal moving parts, no packings, no leakage. Compressed air ballasting eliminates line shocks, permits pressure regulation. Made for all industrial pressures, capacities.

IT DOESN'T COST TO OWN AN ELMES PRESS . . . it pays!

Elmes Hydrolair® Air-Powered Hydraulic Presses

Hydrolairs are the most economical of all power presses to buy and use. No pumps or motors. Powered by shop compressed-air line. Hydrolairs deliver selected pressure and maintain that pressure, even on compressible materials. Available in 30, 50, 75 and 100-ton models, with or without hot plates, and with either hand lever (illustrated) or electric control. Furnished as complete "package" units with nothing else to buy.

Hot Plate Molding Presses

Illustrated is a 450-ton Elmes Hot Plate Press equipped with six single-acting cylinders set into the press bed unrestrained. Rams bear against finished pads beneath the moving platen. Pushbutton control. Press system is arranged so that only two center cylinders may be actuated if desired. Dual-pressure pump provides a high closing speed and moderate pressing speed.

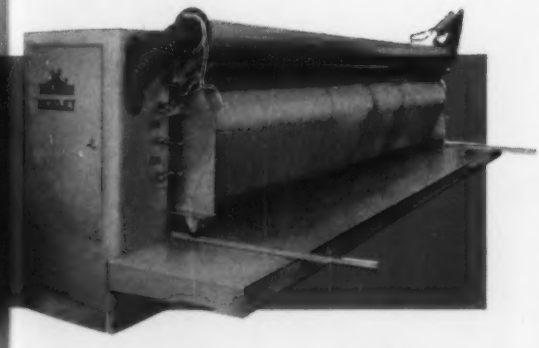
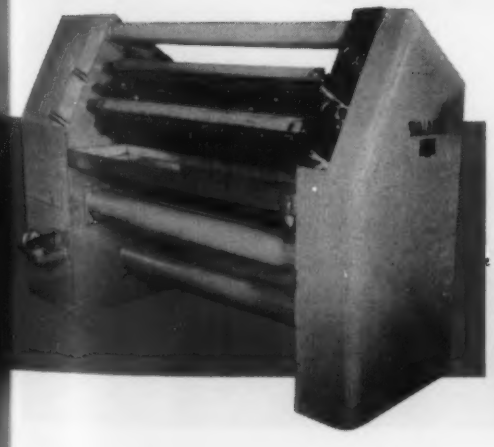
MICROJET COATING LINE



Pioneering Days..



REVERSE ROLL COATING LINE

.130 Years in Web Processing Generally

★ Formations of Plastic Films
★ Decoration of Plastic Films
★ Slitting and Winding
★ Laminating

The John Waldron Corporation has been in continuous business now for 130 years. This in itself might be of only passing interest but for the fact that web processing has always been our business. Even in the earliest days, our business sign could have read . . . 'Designing and Manufacturing Machines for Processing Webs, Sheets or Ribbons'.

Paper came first, followed by rubber and when other plastics began to come into the market, Waldron design engineers were right in the center of things. As the plastics industry expanded—both in kind of plastics and in uses—it was generally a Waldron machine that took care of the web processing steps involved.

Today, the scope of Waldron design and manufacturing service in connection with the processing of plastic webs is as broad as the plastics industry itself. But it is significant that in our whole experience, we have seldom made two machines exactly alike, except for repeat orders. That's the peculiarity of web processing. Rarely are two problems alike, thus precluding the manufacture of so-called 'stock designs'.

Waldron Engineers are fully experienced in all web processing problems. If you have any machine requirement coming up in the near future, why not discuss your problem first with a Waldron engineer? He might be able to contribute something very helpful to your planning.

As a preliminary step to a discussion, send for our general catalog (No. 125) on WALDRON Plastic Processing Machinery.

This DIAL Will Increase Production On Your Extruder

This dial, which controls the Reliance V•S Drive, accurately sets and maintains exact speed control to insure uniform product consistency.

With a Reliance V•S Drive, an extruder lends itself to production of a wide range of materials, regardless of speed requirements.

With the wide speed range of a Reliance V•S Drive you can operate at the highest possible production rates, regardless of material. This wide range of speeds permits the extruder to be coordinated with conveyors, laminators, or any other equipment.

Operating from your plant a-c power source, a Reliance V•S Drive is built to give years of trouble-free performance without costly maintenance.

Whether it's for the extrusion of acrylics, polyethylene, vinyl, or *any* thermoplastic or "cold-set" plastics, a Reliance V•S Drive will help you maintain a more efficient and profitable operation. D-1849

MINI-JECTOR

TRADE MARK

PLASTIC INJECTION MOLDING MACHINES

"Super-Hornet" Power-Operated, Lever-Controlled
One of many models in "Hornet" and "Wasp" Series to suit your needs.

MORE VARIETY at LOWER COST!

Saved: Thousands of dollars in mold costs with versatile, economical MINI-JECTOR. Eliminate "big press" high-per-piece tooling charges!

The more variety, the bigger the savings! Flexible, efficient, MINI-JECTOR Plastic Injection Molding Machines fill your need for low-cost development and production of fast-changing varieties of small molded plastic items. Savings begin with low initial investment of machine (under $1,000) and molds (as low as $29.50). Even more important are the bigger savings in time, trouble and money developing and producing "varieties" of different items by eliminating complex, costly big-press tooling where not required. MINI-JECTOR solves your tricky "insert" molding, too. Compact, simple to operate. Mold cap. 1/3 oz. to 1 oz., all thermoplastics and Nylon. Lever and push-button control models, air or hydraulic power to fit your facilities. Users claim MINI-JECTORS pay for themselves many times over in *savings alone.*

Bring your requirements to Newbury! Our engineers can help you select the model MINI-JECTOR to develop and produce your small (up to 1 oz.) plastic items at lower cost than previous methods.

Write for Catalog today! "Tell-all" booklet, completely illustrated, shows entire line of MINI-JECTOR Plastic Injection Molding Machines and accessories. Learn how MINI-JECTOR adds new flexibility and economy to your plant operations.

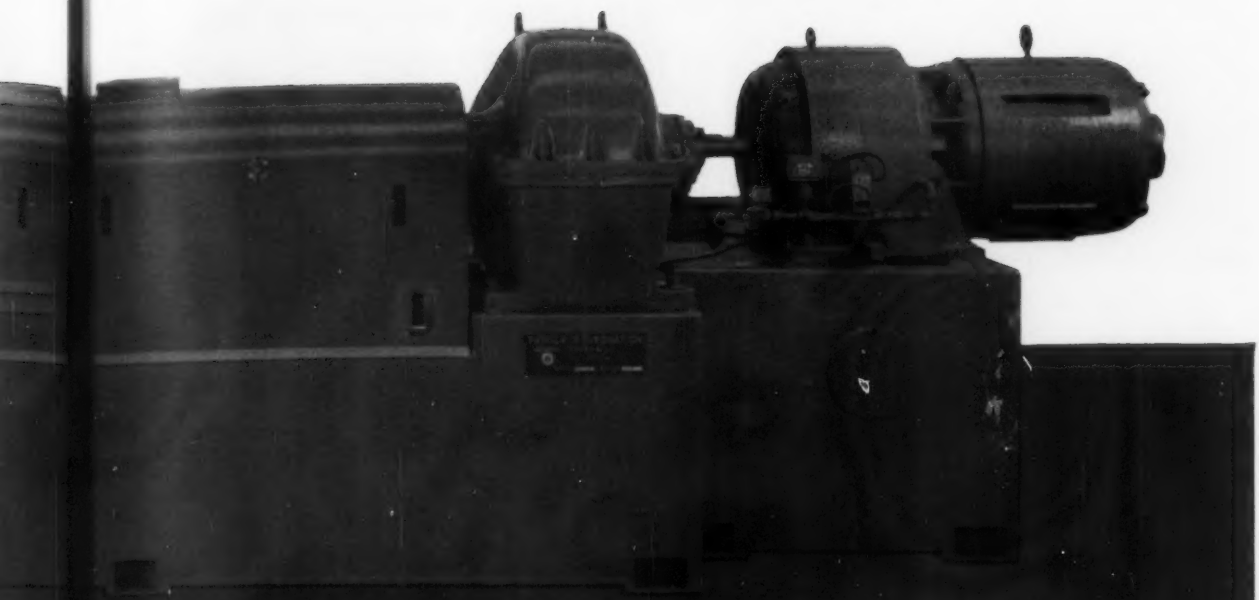
PRODEX EXTRUDERS

PRODEX P.V.P. VENTED EXTRUDERS • L/D 24:1 and 30:1 • are outperforming other machines in leading plants throughout the World.

- ✓ **POLYSTYRENE SHEET** ..... without Predrying
- ✓ **HIGH DENSITY POLYETHYLENES** ..... from Powder Feed
- ✓ **CABLE JACKETING** ..... without Porosity
- ✓ **CALENDER FEEDING** ..... without Banbury or Mills
- ✓ **CONTINUOUS COMPOUNDING** ..... for Wire, Cable, Records and Reclaiming with Excellent Dispersion
- ✓ **DEVOLATILIZING** ..... Continuous Removal of Monomers, Moisture, etc.

PRODEX P.V.P. EXTRUDERS perform these operations within Close Tolerances and at Higher Output Rates



Send for Bulletin E-3, Second Edition, for complete details.

Arrange for a Demonstration today on your Material.

Package Installations for Sheet, Film, Pipe, Wire and Cable, Continuous Compounding and Laminating.

PRODEX EXTRUDERS are available in 1¾", 2½", 3½", 4½", 6" and 8" Sizes.

RS DO IT BETTER . . .

PRODEX NON-VENTED EXTRUDERS • L/D 20:1 and 24:1 • have set New Standards of Performance in Precision and Output Rate when Venting is not required. Sound Engineering and Advanced Instrumentation guarantee Easy and Trouble-free Operation.

- ✓ **GENERAL CUSTOM EXTRUSION** . . . . . for Wide Variety of Compounds and Cross-sections
- ✓ **FILM EXTRUSION** . . . . . Polyethylene and Vinyl
- ✓ **LAMINATING** . . . . . Paper Coating, Plastic to Plastic
- ✓ **VALVED EXTRUSION** . . . . . Interrupted for Molding, Continuous for Dispersions

KEEP TEMPERATURE IN SIGHT WITH AUTO-LITE

Here's your most trustworthy watchman—made by Auto-Lite to chart every change of temperature during operating cycles. Put this recorder to work wherever temperature behavior can affect operating efficiency or product quality.

Newly designed, Model "1000" Recorders with 6" clear reading charts are uniformly responsive throughout their entire temperature range. Various standard ranges from minus 40°F to plus 550°F. Available for wall mounting or portable use. Electric or mechanical chart drive. With capillary tubing for remote reading. Priced from $49.50. Send for new catalog describing Auto-Lite Temperature Recorders and Indicators.

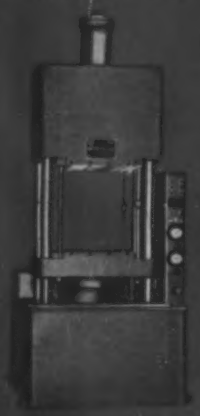
When you're in the market for molding machinery...

WATSON-STILLMAN OFFERS



HORIZONTAL INJECTION MOLDING MACHINES

Automatic and semi-automatic, high-speed machines for molding all types of thermoplastics. Latest features assure flexibility required to mold a wide variety of compounds and intricate parts. Capacities: 5 to 500 ounces.

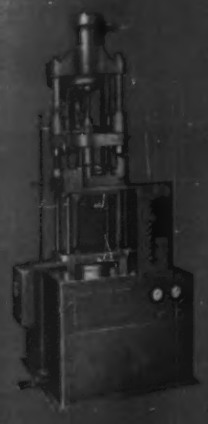
PREPLASTICIZING UNITS

Watson-Stillman preplasticizers give higher capacities, shorter molding cycles, lower injection pressures, material savings and improved product quality. Units can be installed on all standard horizontal molding machines from 16 to 85 ounces.

TRANSFER MOLDING MACHINES

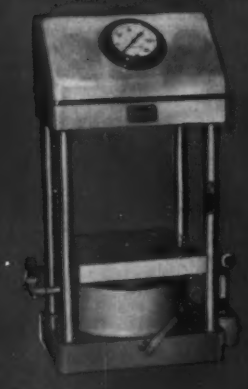
Standard four-column designs incorporating the latest features for molding thermosetting compounds. Ideal for small insert parts and cores. Feature adjustable opening to accommodate a variety of mold sizes. Capacities: 30 to 2000 tons.

COMPRESSION MOLDING PRESSES



Of the same basic design as transfer presses, they can be converted with transfer cylinder. Standard equipment includes bolsters, parallels, degassing, adjustable openings, top and bottom strippers and push-button control. Capacities: 50 to 2000 tons.

GENERAL PURPOSE PRESSES



For molding, laboratory and experimental work or for use as a laminating press. Micro pressure adjustment makes these presses ideal for testing purposes. Electrically operated automatic single-cycle control governs press dwell under pressure. Capacities: 30, 50, 100, 200 tons.

ALL THESE ADVANTAGES:

VERTICAL INJECTION MOLDING MACHINES

Designed to meet the need for low-cost high-speed production of small intricate moldings. In addition, these units are well adapted to molding parts requiring inserts. Capacities: 1, 2, 6, 16, 20 and 24 ounces.

LABORATORY PRESSES

Designed for experimental work and wherever pressures of 30 to 100 tons are required on comparatively small areas. Ideal for die work, laminating and hot or cold molding. Optional electric or steam heating plates. Capacities: 30, 50, 100 tons.

EXTENSIVE LINE

Whatever your production objectives . . . you can meet them from the Watson-Stillman "Completeline" of plastics molding equipment. The line features both standard and special machinery for all applications—in a broad range of sizes and capacities.

ADVANCED DESIGN

Pioneer experience, plus a continuous research and development program, combine to offer machines of consistently high quality and "years-ahead" design. That's why modern efficiency is yours when you specify Watson-Stillman.

ENGINEERING SERVICE

Watson-Stillman engineers have helped thousands of manufacturers to select the right equipment for a specific job – in boosting production speed and efficiency. These men are ready to go to work on your problem, too, with a complete service from press design to final installation.

BROAD BACKGROUND

Established in 1848, Watson-Stillman is one of the oldest manufacturers of hydraulic equipment in the United States and a pioneer in the development of plastics molding machinery.

Next time you're in the market for molding machinery, remember the many advantages offered by Watson-Stillman. In the meantime, send for details of any of the equipment described.

WATSON-STILLMAN PRESS DIVISION

FARREL-BIRMINGHAM COMPANY, INC.

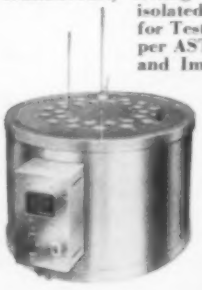
Represented in Canada by Barnett J. Danson, 1912 Avenue Road, Toronto, Ontario
Represented in Japan by The Gosho Company, Ltd., Machinery Department, Tokyo, Osaka and Nagoya

W-S HYDRAULIC

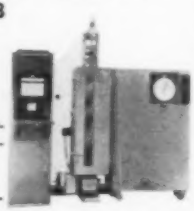
F/B

Farrel-Birmingham also designs and manufactures equipment for processing plastic film and coating. Production units are matched in capacity for planned processing flow. Illustration: Matched production unit consisting of two 3A Banbury mixers two 22" x 60" mills and a 28" x 66" four-roll "Z" Calender. The size and design of the Banburys and mills assure an even flow of properly conditioned material to the calender. Calender is driven by an adjustable-speed motor so that output speed may be regulated according to the gauge of stock being run. Please address inquiries on plastic film processing and coating equipment to Farrel-Birmingham Company, Inc., Ansonia, Conn.

WS-34



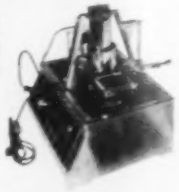
TO TEST PLASTICS AT EXTREME TEMPERATURES
in accordance with ASTM specifications



Scott provides world-standard equipment to determine the usefulness and endurance of synthetic elastomeric materials in modern applications such as jet propulsion, gas turbines, atomic energy plants, etc.

MODEL LG
TEST TUBE AGEING

Tests rubber samples at controlled elevated temperatures up to 550°F. Provides 28 compartments for simultaneously testing a number of isolated specimens for Test Tube Ageing per ASTM D865-54T and Immersion Test per ASTM D471-55T. Supplied COMPLETE with test tubes, closures and vent tubes for 28 chambers. (Also available: Model LGH, to 1000°F).



MODEL L-8
TENSILE

Model L-8 determines stress, strength, percent elongation and resistance to tear of elastomeric materials at temperatures from −70° to 500° F. It incorporates a self-contained conditioning unit with all controls to automatically maintain desired temperature. An illuminated chamber and fully insulated glass door afford full length visibility of the test chamber. For operation at room temperature, door is left open.

MODEL E — BRITTLENESS

Model E Brittle Point Tester with a range of +50° to −120°C is the accepted Industry standard for brittleness determination in accordance with ASTM Designation D746-52T. Portable and self-contained, with all controls to automatically maintain desired temperature. Operates by plugging into standard lighting circuit.

SCOTT TESTERS INC. 103 Blackstone St. Providence, R. I.

STATE YOUR PROBLEM — SOLVING YOUR TESTING PROBLEM IS OUR BUSINESS

Scott Testers — Standard of the World

Plastics Processing Equipment

Pull-Off Unit (Model PO 200) for pulling extruded belting, hose and similar shapes. Can be adapted for rigid pipe, embossing, and slitting. sizes: 4", 8", and 12".

Standard U.S. Vari drive, can be equipped with electronic drive.

Layflat tubing haul-off and surface winder (Model TU 300) has adjustable angle "Vee" assembly and gusseting attachment. Standard sizes from 20" to 96", other sizes on request. Speeds: up to 250 fpm.

Standard electronic drive.

You'll get superior results with the Faeco Constant Tension Turret Winder (Model TW 250), too.
This unit operates on its own electronic circuit, independent of the machine it is linked up with. Result: uniform tension throughout roll build up to finished roll. Winds variety of materials on cardboard tube. Sizes: 26" to 96". Speeds up to 300 fpm. Roll build up: 18" diameter, and larger on request.

Other Faeco plastics processing equipment includes:

- Blown Film Extrusion Dies
- Unwinders
- Laminators
- Casting Roll Units
- Sheet Take Up
- Printing Machinery (Rotogravure and Flexographic)
- Printing Cylinders
- Dry Blenders
- Water Bath Units
- Cooling Trough

Write for detailed information on these high production units.

The new CUSTOM MULTIFRAME TRANSFER
compression molding and laminating press

A modern up-to-date patented hydraulic press designed for the increasingly rugged, severe duty demanded in the plastic molding industry today. Not a redesign of a press made 30 years ago but a completely new, all steel, streamlined, heavy duty press requiring a minimum of maintenance. We can furnish any tonnage, any diameter ram, any platen size, any stroke, any opening—to your exact specifications. Truly a "CUSTOM" press. No questionable castings used. All heavy rolled steel components.

▲ Custom Multiframe Transfer Press with transfer cylinder within main ram. Very popular design due to low overall height and ease of loading mold.

"ENTOLETER" CENTRIFUGAL MACHINES...

assure these Cost Saving Advantages...

- LOW HORSEPOWER REQUIREMENTS
- DIVERSITY OF PRODUCT APPLICATION
- LARGE OR SMALL CAPACITIES
- ADAPTED TO BATCH OR CONTINUOUS SYSTEMS
- DEPENDABLE OPERATION

Operation of the "Entoleter" Centrifugal Machine:

The product is fed by the inlets and distributor to the center of the rotor (A) consisting of two steel discs (B) spaced approximately one inch apart by specially designed impactors.

The material is spun out, by centrifugal force, into a thinning film as it approaches the periphery of the rotor. Powerful uncushioned impact action causes every particle of the material to be thoroughly processed by the "ENTOLETER" CENTRIFUGAL MACHINE.

For descriptive bulletins or information on free application tests in our Development Laboratory . . . contact the ENTOLETER DIVISION, P.O. Box 904, New Haven, Connecticut.

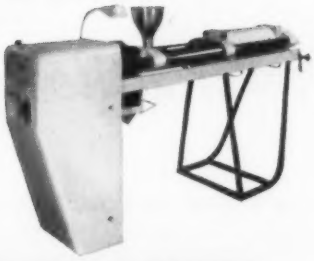
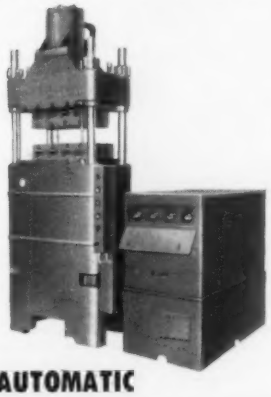
HULL-STANDARD OFFERS



Thermosetting Plastics Molding Presses for Every Purpose!

Hull-Standard Presses—backed by over 20 years of experience in the plastics molding industry and nearly 2000 Standard Presses—now offers you a choice of Standard Presses to exactly meet your molding needs.



COMPLETELY AUTOMATIC COMPRESSION MODELS

New, high speed, cost-cutting press offers you: HIGH PRODUCTION (Cycle less than 12 sec. dry cycle, *plus* large die area, 18" x 18¾"). ECONOMY (Only one operator for up to 10 presses. Low power requirement 3 hp. motor). FLEXIBILITY (Quickset Cycle Control puts press cycling at your fingertips. Wide range of closing speeds to meet requirement. Readily adapted to semi-automatic operation.) SAFETY (Sequence safety interlock protects operator, mold and machine). Sizes 50 to 300 tons.

COMPLETELY AUTOMATIC TRANSFER MODELS

Newest Hull-Standard Press—now available after eight years' design development and proven production performance. Compact design, completely automatic, especially suited to economical molding of small parts demanded by miniaturization in electric and electronic components. Makes possible closer tolerances and more fragile parts. Minimizes flash and finishing costs—particularly on parts with through holes. Model 99-A available, 15 tons clamping capacity.

SEMI-AUTOMATIC COMPRESSION and TRANSFER MODELS

A great money-maker as proved in over 500 molding plants. High speed, semi-automatic. First cost, operating cost and maintenance cost are all *low*. Many exclusive features. Sizes from 50 to 300 tons in compression and transfer types. Write for new brochure.

over 20 years of service to the Plastics Industry

HULL-STANDARD CORPORATION
ABINGTON, PENNA.

EMMETT MACHINE & MANUFACTURING INC.

Now Taylor's international Field many versatile Individual Instruments or

WHAT THIS MEANS TO YOU. The name of the new subsidiary company is Taylor-Emmett Controls, Inc. This means that the products of Taylor-Emmett will now be sold by the Taylor Instrument Companies' sales organization, backed by industry-wide experience of Taylor application and design engineers and full facilities of Taylor research. Emmett instruments have earned a fine reputation in the plastics and rubber industries. They incorporate great engineering ingenuity in their compactness, interchangeability of parts permitting small inventories and their simplified construction. The fact that they are now available through your Taylor Field Engineer will mean experienced help on your processing problems and prompt service when required. Write for catalog to Taylor-Emmett Controls, Inc., Akron, Ohio, or Taylor Instrument Companies, Rochester, N. Y.

Mastertrol Control Center for timing and bumping, is a centralized unit for controlling the operation of 16 molding presses, including spare plug-in unit and test station. Puts quality control in the hands of supervision, independent of the whims of individual operators.

Type D765 Robotron Timer —the complete timing control for plastic molding presses. Panel is so simple that any possible cycle sequence can be set up in as short a time as 10 seconds, without particular skill or familiarity.

Two Pressure Fully Balanced Automatic Hydraulic Valves. "Never-Grind" Construction, cylinder-operated. 35 to 100 psi. Adjustable speed check for L.P. 75 to 1,000 and H.P. 4,000 to 6,000 psi. Sizes ¾ through 4". Normally Open; Normally Closed and 3 Way Fully Balanced.

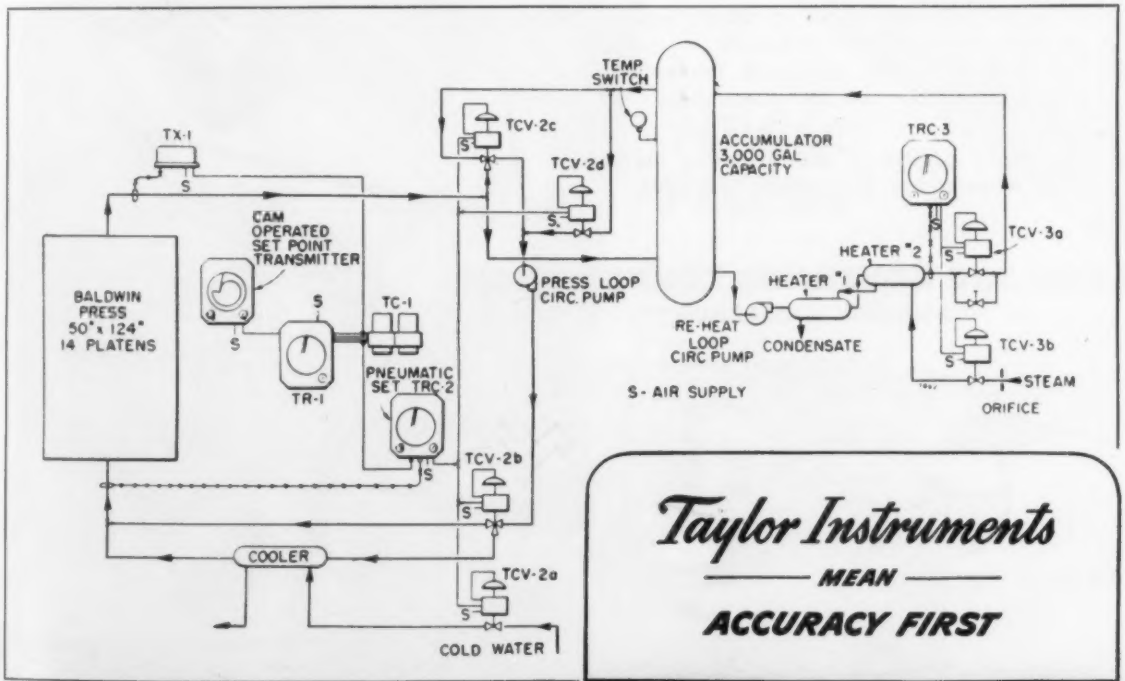
Diaphragm Operated Valves. Air-operated. High capacity in Normally Open, Normally Closed, 3-Way and Normally Open V-Port types. Pressures to 300 psi. Bronze, cast-iron or steel bodies. Any trim. Also available with cylinder operators.

3500-lb. Three Way Valve. Type 380 balanced Three-Way Hydraulic Valve is cylinder operated, compact and has a high capacity. Pressure may be applied to any port connection, due to the valve's balanced design. "Never grind" feature. 35 to 100 psi. air pressure.

3500-lb. Two Way Valve. Type 370 balanced Two-Way Hydraulic Valve is cylinder operated, compact and has excellent capacity. Available either normally open, or normally closed. Normally operated at 35 to 100 psi, air pressure.

MERIT

Taylor-Emmett Controls, Inc.



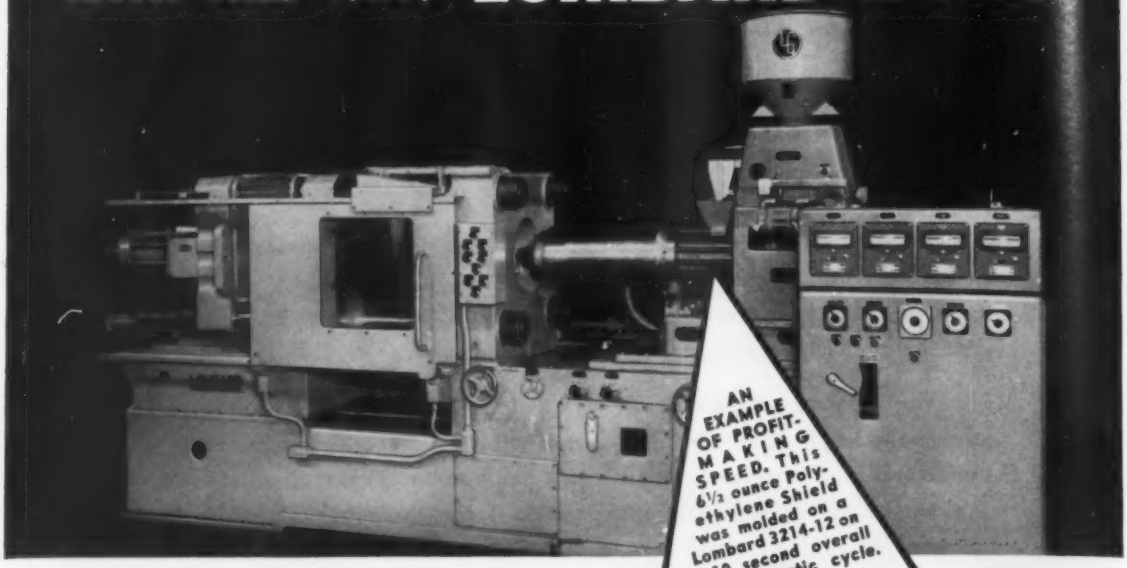
A SUBSIDIARY OF *Taylor Instrument Companies*

BECOMES PART OF **TAYLOR INSTRUMENT COMPANIES**

Engineer organization will provide completely coordinated Control Systems

PRODUCING high quality laminated plastic sheets demands a safe, dependable, and fully controllable heating and cooling system. A well-known Eastern company has solved this problem with the use of a fully automatic system, using Taylor controls. See schematic below.

Maybe your control problem is different from this one, but here is an interesting example of successful cooperation between user, equipment manufacturer, and instrument engineer. When you buy Taylor instrumentation, you're also buying years of experience and technical skill, that pays off in greater quality control and lower operating costs. For further information, see your Taylor Field Engineer, or write Taylor Instrument Companies, Rochester 1, N. Y., or Toronto, Canada.



Fully automatic heating and cooling system provides for low peak demand on steam supply, and enough reserve heat storage capacity to carry one complete press cycle.

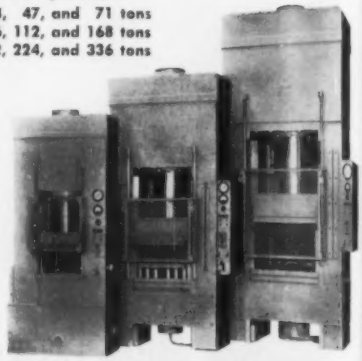
Compression–Transfer Presses

Users report up to 20% higher production with a Bipel Press installation! "Auto-Control" replaces hit-and-miss judgment, permits use of semi-skilled labor with more cycles, almost no rejects!

B.T.H. Ltd., England



***FEATURES:* Fewer Rejects** . . . "Auto-Control" reproduces even the most complex molding cycle, including provision for breathing and dwell. Production of usable pieces usually 100%. **High Output** . . . operator merely loads preform, presses button. Automatic control eliminates time lost clearing over-cured moldings, cuts stripping and reloading time (especially for small multicavity components). Result: several extra cycles per hour. **Low Maintenance** . . . mold pin breakage reduced because of slow closing speeds. Special unloading valve which cannot bypass fluid under pressure, but always unloads, safeguards hydraulic system. Basic operating pressure of only 1000 psi, saves wear and tear, with pressure doubled or tripled *within* the press. **Drive Systems** . . . central, out-of-the-way system for multiple installations, or built-in for individual presses. **Close Temperature Control** . . . induction heated platens (available for your present presses, too) mean closer control and more effective heat transfer to work. **Choice of Pressures** . . . 3 sizes available.

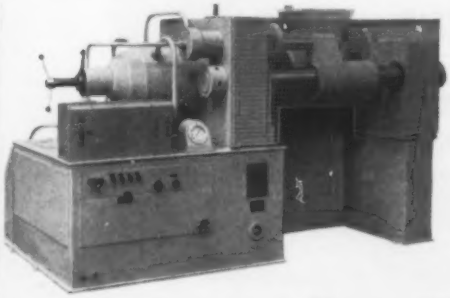
BRAND NEW FULLY AUTOMATIC PRESS *(left)* occupies only half the usual floor space! Very fast feeding and stripping action; easy changeover from top to bottom ejection, automatic to manual operation. Automatic units swing to side for free access to molds. 2 models available with up to 71 or 168 ton capacities.

BIPEL Presses available in 3 models, each offering a selection of 3 pressures:

TYPE 40: 23, 47, and 71 tons
TYPE 100: 56, 112, and 168 tons
TYPE 200: 112, 224, and 336 tons

B.I.P. ENGINEERING LTD.
Sutton Coldfield, England

In Canada: John Sperling and Company
[illegible]

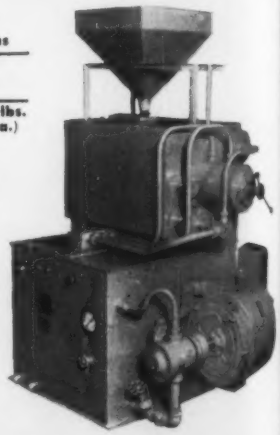


BIPEL®

AMERICAN INQUIRIES TO:
RALPH B. SYMONS ASSOCIATES, INC.
[illegible]

***FEATURES:* Uniform Density** . . . die rides free during compression, allowing equivalent pressure on *both* punches. This, plus accurate hydraulic loading, insures constant uniform density. **Preforms Any Powder** . . . main ram compresses powder only, with *steady squeeze*, not mechanical blow. Complete control for amount of "dwell" or pressure desired.

maximum pressure	13 tons	39 tons	78 tons	155 tons
maximum strokes per hour	2600	1500	850	600
typical preform weight	.2–1.2 oz. (1½" dia.)	3.7–8.1 oz. (3" dia.)	8.3–18 oz. (4½" dia.)	10 oz.–6 lbs. (6½" dia.)



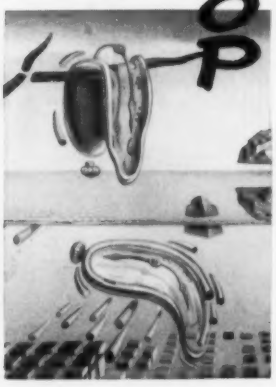
*based on average powder density of .35 ozs. per cubic in.

M.K. Electric Ltd., England

Double pressing arrangement available to allow for escape of air in preforming difficult powders. **Damage-proof Operation** . . . no moving parts come between punches. **Clean, Quiet** . . . fills from *within* hopper for dust-free, quiet operation; can be cleaned in minutes between runs. **Labor Saving** . . . finished preforms are so firm that they may be discharged into tote boxes or drums unattended. One operator can easily supervise several units. **No Powder Loss** . . . all powder is preformed, no spillage. **Higher Production Rate** . . . from multiple punch sets; punches for special shapes available. **Controls** of all operating variables located conveniently for instant settings. **Service** . . . all normal replacement parts in stock for immediate shipment if needed. Electricals to suit.

155 TON UNIT *(left)* has 7½ inch fill depth, can produce large preforms up to 6½ lbs., handle a ton of material per hour.

Write for complete details. Demonstrations and Full Service at Tiverton.



Controlled hydraulic operation with high production speeds are possible only with Bipel! Unmatched versatility, performance and speed . . . clean and quiet . . . Bipel Preformers can produce preforms up to 6 lbs. ea., or small preforms up to 25,000 per hour!

Horizontal Hydraulic Pelleters

INJECTION MOLDERS
DON'T LET YOUR MOLDING PROFITS DROOP

STOP LOSING TIME WITH OLD STYLE HEATERS

Here's What IMS REPLACEMENT HEATING CYLINDERS *Will Do for You*

PROVEN IN USE

These inside glimpses of IMS cylinder design explain why more and more molders are replacing old cylinders with IMS Heating Chambers.

IMS Extra Capacity Heaters bring down molding and maintenance costs. Reeds, Watsons, HPM's, Impco, Fellows and many other machines -- over 700 in all -- in sizes from 4 to 85 ounces, are now equipped with IMS Long-Life Superheaters.

SIMPLICITY IN CONSTRUCTION

Our three heater sections (front, spreader and rear) require a minimum of critical tolerances. Ample seat area is used, but seats are not so wide as to spread the available load too thin. Perfect registers, self-reenforcing overlap at joints, with correct crown on seat are the secret of IMS leakproof seals.

There are no sleeves -- no gaps -- no press fits to interfere with uniform heat transfer, or to expand unevenly, causing leaks or hot spots.

STREAMLINED DESIGN

Integral Spreader Unit permits maximum internal streamlining consistent with elimination of sharp fins or points where burning can occur. Uniform flow through IMS Heaters is assured because all internal sections are designed to pass material evenly -- no place for plastic to stick or lag. Heated spreader unit is the most efficient plasticizer commercially available today!

LEAKPROOF WELDS

IMS uses a special HOOK JOINT weld that locks the cylinders together far tighter than is possible with bolts or threads. Our Hook Joint holds better because it is located closer to the seat area than any other fastening method, and eliminates most of the leverage that starts leaks in other cylinders.

CUTS REPAIR COSTS

Repair costs are usually one-half to one-third less than with other cylinder types. And cylinder life is usually from 2 to 5 times that of most original equipment units. Year in, year out your downtime is less with IMS Leak-Proof Replacement Cylinders.

There's New Profit in Old Presses with IMS Extra Capacity Superheaters

ROYLE EXTRUDERS for RUBBER, PLASTICS, WIRE INSULATING

Dependable, economical, 'round-the-clock production is assured with Spirod or Spiroyle extruding machines. They are the result of more than three-quarters of a century's experience in the design and construction of extruding machines in which time-tested features have been incorporated to provide maximum productivity with minimum operating cost.

SPIROD®

an electrically heated extruding machine with high velocity evaporative cooling. Although designed to supply and hold the accurately zoned higher temperatures required in processing today's plastic compounds, Spirod is an all-purpose extruding machine for either rubber or plastics.

SPIROYLE® extruding machines designed for processing where the use of a circulating heat transfer medium is desired for sensitive operating temperatures.

Both SPIROD and SPIROYLE extruding machines are available in standard sizes—1⅛" through 12" cylinder bore.

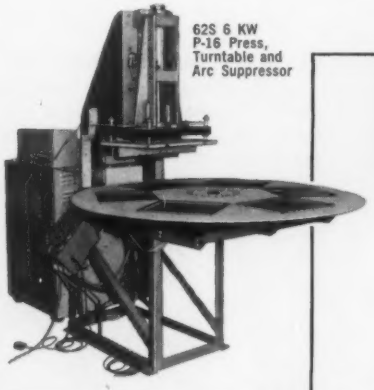
Thermatron*

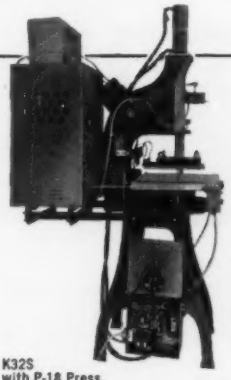
*Reg. U. S. Pat. Off.

Industrial Electronic Generators and Heat Sealing Presses



Electronic welding of vinyl plastics by Thermatron is rapidly replacing older, less satisfactory methods throughout the world. The dynamic force developed in these generators *welds* – does not stitch – plastic in seconds, to produce seams stronger than the material itself . . . air-tight and water-tight.

Standard electronic generators and presses from ½ KW up to 500 KW can be supplied with almost any degree of automation desired to weld vinyl from .002" to .080" as well as plastic foam, quilted vinyl sheeting and other special materials. Also available are completely automatic feeds incorporating turntables and conveyor systems so that the plastic may be welded, cut and embossed in a single operation.



Thermatron units are sold under one contract and one responsibility, which covers survey, generator, press, electrodes and their installation. Presses of custom design and electrodes built to order for special requirements. A few of the many models available are illustrated. For further information, write for our latest bulletin MP.

Extruders:

BEFORE YOUR JOB

Robbins Combination Haul-Off & Shear Unit

This unit can be combined as shown, or the chromium roll and rubber roll can be mounted on individual bases for positioning that best fits your needs. Can be used with all makes of extruders now on the market.

Robbins Dies

Robbins produce dies for all types of extrusions. The one illustrated was engineered for rigid materials and within 3½ hours after the initial start up it was producing a quality product.

Sheet Polishing Unit

This Robbins Sheet Polishing unit helps you three ways: (1) More uniform product—eliminates wrinkle and pit holes. (2) Retains finish after vacuum forming. (3) Cuts costs.

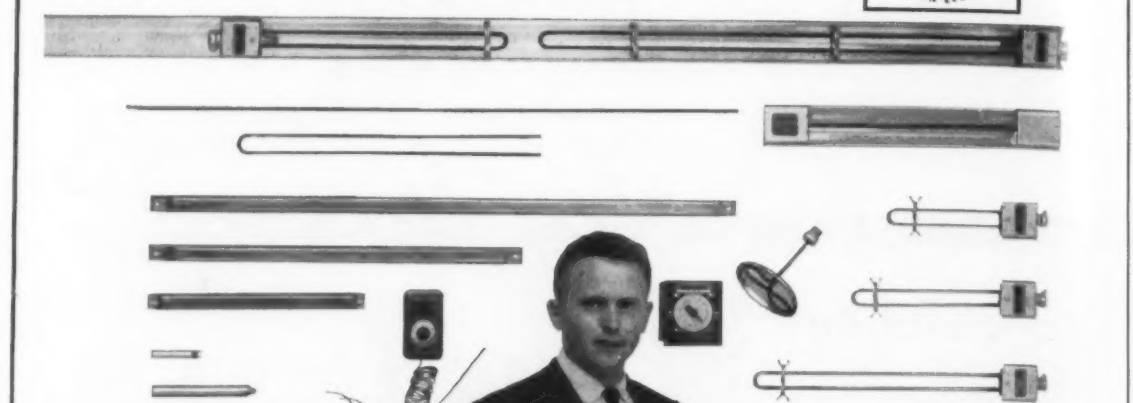
Robbins
never say die . . . say Robbins die

PLASTIC MACHINERY CORPORATION

We specialize in the design and building of special type dies and haul-off equipment for the plastic extrusion field

GOES ON THE BOARD...

...let our "board" go to work for you



Not miracle men... but a capable group with imagination, creative drive and practical experience who specialize in the production of dies, haul-off and other special equipment for the plastic industry. Simply, here is ability... ability that can be of invaluable help to you in this highly specialized field. *Use it!*

Robbins standard line of equipment includes: sheeting dies • haul-off rolls • traveling shears • wind-up units • pipe dies • water tanks • pipe pull-offs • pipe coiling machines • traveling cut-off saws • profile dies • conveyors • splicing machines • cut-off machines.

Want quick, economical solutions to your heating problems?

Call the Chromalox man for the **ANSWERS**

No matter what heating problem you have, there's a Chromalox electric heating unit of the type and size you need.

Your Chromalox Representative—the man with the answers to your heating problems, routine or unusual—can provide you with the plastic industry's only complete heating line.

Over 15,000 standard types, sizes, and ratings to choose from—plus a complete range of controls and accessories—give you the best answer for your specific job. For instance . . .

- With Chromalox Electric Far-Infrared, you get fast, uniform heat dialed to your exact need from 4 to 100% of heater capacity. The elements are metal-sheathed and unbreakable, and provide color-blind, uniform radiation.
- Easy to install strip heaters come in lengths up to 96 inches. Available curved lengthwise or in cross-section, as well as new half-circle, high-temperature refractory-insulated heater bands designed to clamp on injection and extrusion barrels.
- Chromalox Electric Cartridge Heaters provide more dependable spot heat with close thermal control. Exclusive design gives positive lead wire protection against flexing, abrasion, moisture.

For an on-the-spot heating analysis at no obligation, just call your Chromalox Direct Factory Representative. He is backed by Edwin L. Wiegand Company—the world's largest manufacturer of electric heating apparatus. A call to your "man with the answers" (see listing on opposite page) will put Chromalox Engineering Service to work for you.

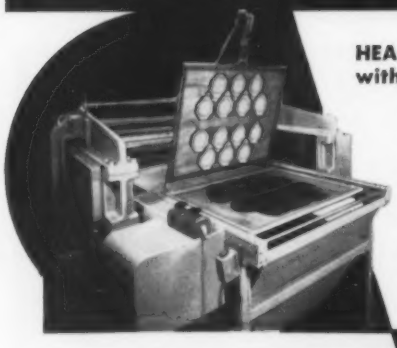
Schematic sketch of the control circuit in the Sarcotrol Model MC-1, Single Unit. Model MC-2, Dual Unit, is equipped with two of these circuits, MC-3 has 3 circuits.

Before you buy...Compare
all Temperature Control Units for molds, rolls, cylinders, drums

COMPLETELY redesigned, the new *Sarcotrol* heating and cooling unit is fully automatic as shown in the following list of features. It maintains even face temperatures by recirculating temperature-controlled water at high velocity through molds or roll jackets. Check *Sarcotrol's* features against any other unit *before* you buy.

Sarcotrol gives you *all* these features

- **Dependability** — built and guaranteed by Sarco, makers of temperature controls and steam traps since 1914.
- **No need for special heat transfer liquids** — temperature-controlled water to 300° F. is recirculated at high velocity in closed system.
- **Independent circulating systems** — the Sarcotrol is available with one, two or three independent systems (see above sketch).
- **Simple, sensitive control** — one knob changes temperature control setting; sensitive thermostat (±1°) minimizes temperature lags; easy-to-read dial shows both desired and actual temperatures.
- **Automatic selection of heating rate** — for fast heat-up; then close control.
- **Saves electricity and water** — the *same* thermostat regulates both *rate* of heat input and cooling; cuts out both when set temperature is reached.
- **Automatic heater protection** — heaters are automatically cut off when pump is shut down.
- **Many other features** — are listed in the *Sarcotrol* technical bulletin.



2178 F

Please advise if you are interested in automatic temperature control for molds or for rolls. Technical bulletin and case histories will be mailed to you by Sarco Company, Inc., Empire State Building, New York 1, N. Y.

SARCO

Improves product quality and output

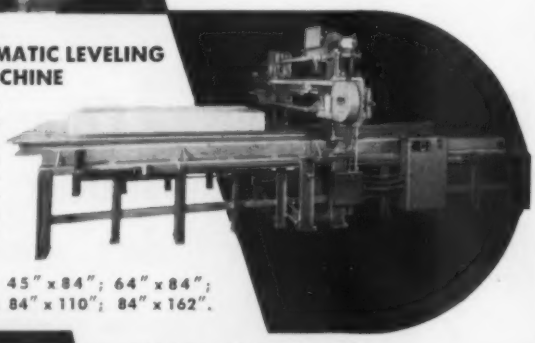
DEPEND on FEMCO *for the BEST*
DIE CUTTERS AND SPLITTERS

HEAVY DUTY ROLLER DIE CUTTER with AUTOMATIC Load and Unload

Fully loaded frame and dies automatically move onto bed of Die Cutter; parts are die cut; frame and dies move off bed; die cut parts drop into hopper and tote box. Equipment fits FEMCO Roller Die Machines with bed sizes 48 x 42; 48 x 72; 48 x 84. Designed for continuous production trimming of molded rubber goods and small automotive parts.

Single Head AUTOMATIC LEVELING and SPLITTING MACHINE

For Polyurethane, Polyvinyl Foam and similar Plastic Foam materials. This automatic machine requires only one operator, man or woman. Levels slabs 12" high, then reduces slab to sheets thin as ⅛", thick as 2".



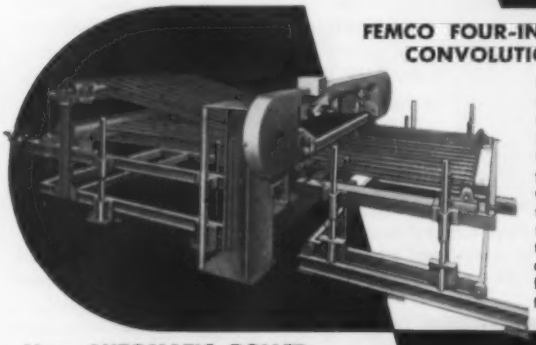


Table sizes: 45" x 64"; 45" x 84"; 64" x 84"; 64" x 96"; 64" x 110"; 84" x 110"; 84" x 162".

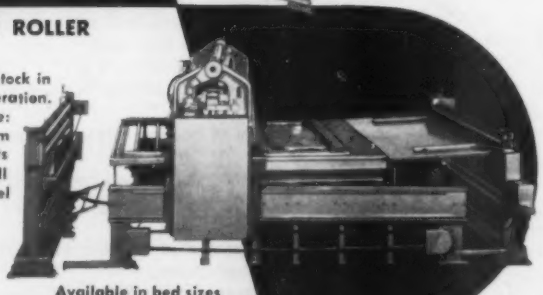


FEMCO FOUR-IN-ONE CONVOLUTION MACHINE

Combines features of Cushion Cutter, Models 65-78 Splitter and single head conveyorized Slab Cutter; also makes corrugated cuts of Polyvinyl and Polyurethane stock, slabs or rolls. Levels and splits slabs (max. 15" thick) into sheets as thin as ⅛". Handles slabs 9 ft. long. Splits roll stock thin as ⅛".

New AUTOMATIC ROLLER DIE CUTTER

Die Cuts parts from roll stock in automatic continuous operation. High production. Example: This machine has cut foam rubber cloth-backed parts 25 per minute from roll stock, using a 6 cavity steel rule die. Push button, machine automatically operates until entire roll of stock is die cut.

Available in bed sizes 72 x 66 and 84 x 72.

The FALLS ENGINEERING AND MACHINE CO.

Established 1917

1734 FRONT ST., CUYAHOGA FALLS, O.

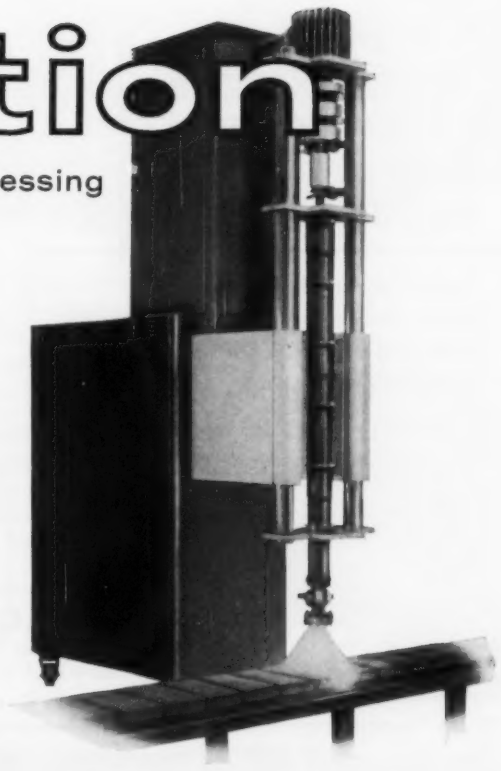
FEMCO Builds 22 Special Machines for the Rubber, Plastics and allied industries. Write for folders, prices on machines shown here or inquire about others.

CAMBRIDGE SURFACE PYROMETERS for the PLASTICS INDUSTRY

♦ The routine use of Cambridge Surface Pyrometers takes the guesswork out of surface temperature determination. Cambridge Instruments are accurate, dependable, rugged, quick-acting and easy to use. The Roll Model is for checking surface temperatures of still and moving rolls. The Needle Model is for insertion into preforms and materials in a plastic or semi-plastic state. The Mold Model is for checking surface temperatures of mold cavities.

♦ For money-saving and better plastic-making suggestions, write for Bulletin 3528. It gives detailed information on these instruments.

CAMBRIDGE INSTRUMENT COMPANY, INC.



3528 Grand Central Terminal, New York 17, N.Y.

PIONEER MANUFACTURERS OF PRECISION INSTRUMENTS

Electron, X-ray or Neutron

radiation

for research or commercial processing

ARCO manufactures fully-developed, tested electron linear accelerators and positive ion accelerators, and also offers you comprehensive irradiation services and facilities. This service includes assistance in establishing irradiation facilities in your laboratory or plant and actual experimental investigation and processing in ARCO's Walnut Creek, California irradiation facility. Another irradiation facility is being built in Rockford, Illinois for the use of Eastern and Midwestern organizations.

At ARCO, your requirements will receive the attention of a widely experienced technical group—men whose professional careers have been devoted to research and production application of radiation.

NEW CATALOG GIVES DETAILS, APPLICATIONS

Write today for new catalogs describing ARCO accelerators and radiation service facilities.

ARCO Mark 1-F4 Electron Linear Accelerator

Brief Specifications - ARCO Accelerators

Electron Linear Accelerators	Mark I Series	Mark 20 Series
Electron Beam Energy	2 to 12 Mev	up to 50 Mev
Electron Beam Power	1 to 10 Kw	up to 60 Kw
Max. X-ray Intensity (1 meter)	1.2×10^6 rad/hr	10^8 rad/hr
Max. Fast Neutron Production	2×10^{12}/sec	10^{14}/sec
Max. Thermal Neutron Flux	10^9/cm²/sec	2×10^{11}/cm²/sec
Max. Capacity (100% Utilization Efficiency)	7,800 Mrad-lb/hr	47,000 Mrad-lb/hr
Max. One-side Penetration in H_2O (± 10% dose variation)	3.5 cm	

Positive Ion Accelerators	
High Current Neutron Generators	
Max. Beam Energy	500 Kv
Max. Beam Current	400 μa
Max. Neutron Yield (14 Mev - D-T reaction)	10^{11}/sec
High Energy Positive Ion Linear Accelerators to individual specifications

American Agile Fabricating Equipment Opens New Fields For Plastic Application

Complete PLASTIC WELDING KIT

"Do-It-Yourself" plastic welding kit permits fast, easy fabrication and repair of plastic components and weldments. Easy to use, the kit contains all necessary tools and supplies — 110-V. welding gun, 15′ nitrogen hose, Nitrogen flowmeter, contour marker, porosity spark tester, marking crayon, knife . . . plus, two simplified instruction books that guarantee successful welding.

Apply Corrosion-Resistant Plastic Coatings With The Fluidizing SPRAY & DIP COATING UNIT

This mobile, dual purpose unit called the Mark III, permits spray or dip coating of metal targets with corrosion-resistant coating using finely divided polyethylene powders. 33½″ high x 20″ wide, unit consists of metal reservoir, 15″ in dia. with 24″ deep powder bed. It is easily moved by one man and can be attached to any available compressed air line.

In addition to the application of polyethylene powder, the fluidizing process can be also used to apply nylon and fluorocarbons, thus increasing the flexibility of the unit.

Orders filled promptly from stock, or write for further information.

Reinforced Plastics

These presses are specially for polyester/glass or asbestos/phenolic or epoxy resins. The 250-ton press shown has a table size 8 ft. x 5 ft., daylight 8 ft. and stroke 4 ft. Vickers pumping equipment is mounted on the head and the rate of closing is adjustable down to very slow speed at any point desired on the stroke. The tables have tee slots for mould securing and are water cooled.

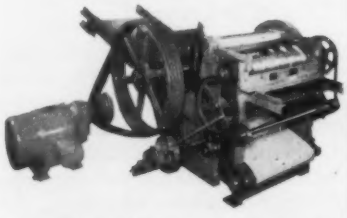
TAYLOR-STILES PELLETERS

CUT FROM 1/8th" CUBES
TO 5" x 5" x 1" BLANKS

●



Cut up to 10 TONS of
PLASTIC PELLETS per hour!

Practically every plastic manufacturer of importance in the United States today is using Taylor-Stiles Cutters for dicing its stock. In some instances the material comes to the machine in a continuous sheet which may be up to 13½" wide. In other installations, the stock is in the form of rods which the 12 or 24 knife head of the Taylor-Stiles 700 Series Cutter shears off into pellets. Production rates on ⅛" cubes in some instances is as great as 10 tons an hour.

●

Cut 4648 —
5"x5"x1" SQUARES per MINUTE

A Taylor-Stiles #224 "LITTLE GIANT" Dicing cutter will cut 21" wide sheets into 5" wide strips and then cross cut these strips into 5" squares at the rate of 4648 squares per minute.

Other Taylor-Stiles Cutters are used for cutting latex.

●

JOB ENGINEERED KNIVES

Taylor-Stiles Knives keep their edge for amazingly long periods of time. When sharpening is necessary, the straight-edge design of Taylor-Stiles knives makes for quick and easy sharpening.

Engineered to your present needs... Designed for your future expansion...

A FULL

To help you keep pace with the plastic industry's rapid expansion, Reed-Prentice carries on a continuing program of engineering research and development. As one result of this pioneering, the REED line is now the first offered by any manufacturer to bring you *both* injection molding *and* extrusion equipment.

Check this timetable and you will see why, over the last four years, eight REED engineering advances have pointed the way to faster, more economical production.

1953 – 450T – 20/24 oz. REED designed . . . rugged, fast, dependable.

1954 – 175T – 4/6 oz. REED . . . introduced for high-speed, automatic molding.
– 400T – 16/20 oz. REED . . . offered extra-capacity operation.

1955 – New REED-SPEED heater, with tapered spreader design, brought faster, more thorough plasticizing.
– 300TA-1/2/16 oz. REED . . . a complete redesign that helped slash molding costs.

1956 – New 275T – 8/10 oz. REED . . . with higher speed, more capacity, greater versatility.
– 600T – 32 oz. REED . . . new injection end design increased speed 72%.
– REED *Autoflow* marked the Reed-Prentice entry into extrusion with a revolutionary new principle of operation.

Backed by this record of leadership – every machine in the line either new or fully redesigned within the last four years – you can expect top value in a REED. Engineered into each of the six injection models you will find:

- **Versatility** . . . with positive mold clamping pressure that minimizes flash, adjustable mold clamping stroke, and provision for fully automatic operation.
- **Fast plasticizing** . . . REED-SPEED heater, standard on all machines, gives you top capacity and speed.
- **Ease of operation** . . . with centralized controls and hydraulic adjustment of die space and plunger housing.
- **Rugged construction** . . . because fabricated steel bases are built for extra strength and rigidity.
- **Safer** . . . with interlocked front safety door and large rear guard.
- **Simple to maintain** . . . manifold type valve mountings and complete accessibility of all parts reduces maintenance problems.

In the new REED *Autoflow* extruder, you get five distinct advantages over conventional machines. The *Autoflow* gives you greater output in pounds per horsepower per hour, plus outstanding ability to color and compound. Its precise speed and temperature control, combined with balanced working pressures and fast through-put at the plasticizing area, mean a more even flow of higher quality product, especially when you are working with heat-sensitive materials.

At Reed-Prentice headquarters, there is a 51-man Engineering staff devoted to further development, application and testing of equipment. This backs up the coast-to-coast REED sales and service organization, helps assure you of getting better equipment specifically designed to your present *and* future needs.

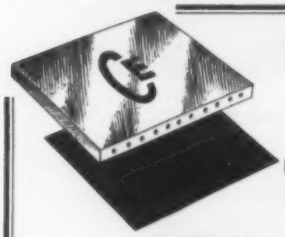
FLAWLESS MOLDS for . . .

INJECTION
COMPRESSION
TRANSFER
FIBERGLAS AND
PREMIX MOLDING

This sharply detailed television mask mold was expertly made by Anson—using a 16 x 30 Cincinnati Hydrotel, working from blocks measuring 5 x 29 x 40 inches.

- Anson precision-engineered molds give ultra-smooth surface finishes to your molded parts.
- Anson's industry-famous polishing department can be relied upon for mirror-like optical finishes.
- Anson design engineers have all served formal apprenticeships in the tool and die industry.
- Anson maintains a wide range of specialized equipment for all types of molding problems.
- Anson has a long established reputation for prompt delivery.



That's why so many automobile, refrigerator, radio, television, and small appliance manufacturers, from all over the country, specify Anson molds for their products.

TOGGLE CLAMPS Boost PRODUCTION

Any time you need a work-holder for plastic parts for shaping, cementing or any other phase of processing, you will find a DE-STA-CO Toggle Clamp to fit the need! Further, DE-STA-CO's bring you extreme flexibility in fixture design!

Also, many Clamps are available in aluminum (for lightness) as well as steel. Air-operated Clamps are among the many new and original models which are also now available.

For complete 40-page DE-STA-CO catalog, full information on any Clamp or for assistance on any tooling problem . . .

CALL ON YOUR NEAREST DE-STA-CO STOCKING DISTRIBUTOR!

JOANNA STOCK SHELLS and SHIPPING CORES

can cut your inplant stock winding and shipping costs!

3 different types

A—Aluminum MILL ROLL and WINDING CORES . . . for lightweight inplant stock winding

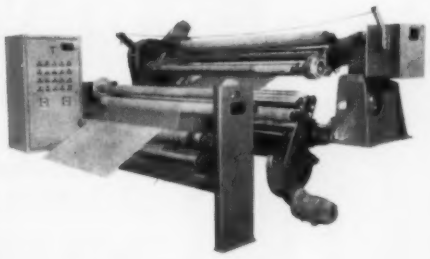
Easy-to-handle cores, yet exceptionally sturdy for rugged material winding applications. Cores have square hole insert of *steel* tubing—which will not wear. For any type shaft. Diameters up to 10" O.D., any desired lengths.

B—All-Steel MILL ROLL and WINDING CORES . . . for heavy duty inplant stock winding

Rugged, life-time cores, made of durable steel tubing. Ends will never wear! Furnished with any size tubular steel insert for fast, easy locating and winding on any type shaft. All sizes up to 6" O.D.

C—Metal End PAPER CORES . . . for low-cost, safe shipping of all types of plastic materials

Lightweight, low-cost, *returnable* cores with welded, reinforced ends —of 16 and 20 gauge steel. Ends have 1¼" opening for square bar. Standard dia.—3½" O.D. with ¼" wall, any desired length.



JOANNA STOCK SHELLS (A, B) save time and protect materials in all inplant stock winding applications. JOANNA SHIPPING CORES (C) prevent damage in transit — plastic sheeting, etc., stays in factory-fresh condition.

Let experienced CORE SPECIALISTS save you time and money—whatever your inplant or shipping problems. You always get prompt service — even for special custom-made cores. WRITE OR CALL FOR INFORMATION AND QUOTATIONS TODAY!

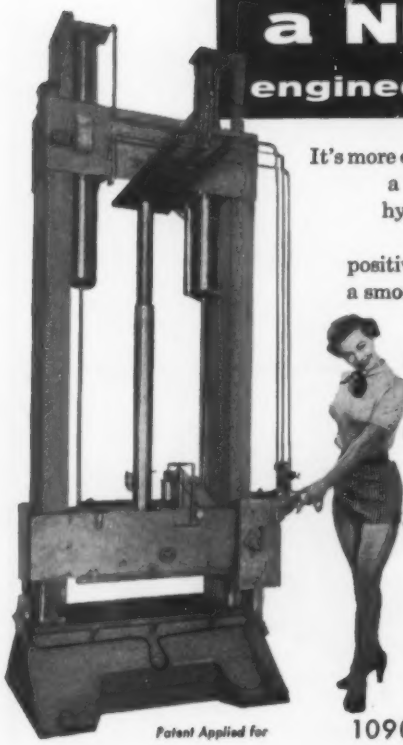
INSURES UNIFORMITY with PRECISION ACCURACY... .001" TOLERANCE, VASTLY INCREASED PRODUCTION



Eliminates dirt and grit. Handles thick or thin materials up to 50 inches wide with sufficient H.P. for sizeable cuts. Provided with variable feed suitable for a wide range of materials. Built-in knife grinder and other features for minimal maintenance.

BUSS MACHINE WORKS *Planer Specialists Since 1862*

300 EIGHTH STREET, HOLLAND, MICHIGAN

a NEW press design

engineered specifically for the industry

It's more economical to own and operate a D-K Hi-Speed Molding Press. By utilizing a combination of air and hydraulic pressure with simplified, self-contained hydraulic system, expensive separate pumping units are eliminated. The result is a press with a larger, more accessible working area, positive control with fine adjustments on both fast and slow closing speeds and a smooth flow of power. Extremely fast closing speeds are achieved, facilitating use of more highly catalyzed resins and a faster curing cycle.

LOW INITIAL COST . . . through simplified design, skillful engineering and the elimination of complicated mechanical devices.

LOW OPERATING AND MAINTENANCE COSTS . . . Power requirements are less by utilizing a combination of air and hydraulic pressure with a minimum of moving parts.

VERSATILITY . . . Stroke, daylight openings and pressure can be furnished in a wide variety of combinations; platen, heated or cold, can be furnished to customer's specifications.

Patent Applied for

Check Actual Stock Temperatures Quickly Accurately

With T-E's Three-Unit Package

COURTESY—NATIONAL RUBBER MACHINERY CO.

Checking stock temperature with T-E's three-unit package

"MiniMite" Pyrometer Indicator

For fast, convenient and highly accurate quality control of plastic extrusions—T-E's three-unit, temperature measuring package is ideal. With it you can check actual stock temperatures—and then correlate these to controllers for correct settings. It helps you avoid production losses during start-up or when ambient conditions vary. The package includes T-E's (1) "Plastic Melt" thermocouple, (2) "MiniMite" Portable Pyrometer Indicator and (3) extension wire with jack connector. With the "Plastic Melt" thermocouple installed in the extruder, the "MiniMite" can be connected in seconds to provide a rapid reading. Accurate to ¼ of 1% of scale range, the four lb. "MiniMite" can also be used to check other thermocouples or to calibrate controlling instruments.

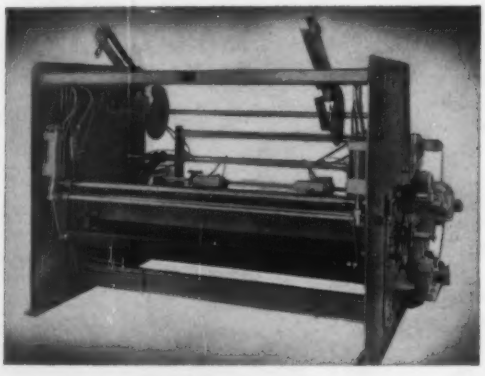
T-E's "Plastic Melt" Thermocouple

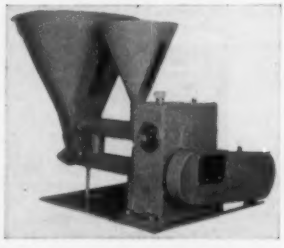
AUXILIARY MACHINES FOR HANDLING EXTRUSIONS



While what occurs inside the extruder has a great effect on the finished extrusion, you cannot overestimate the importance of the handling it receives once it leaves the die. Cooling, tension, take-up and spooling all have a decided effect on the success or failure of your operation. Progressive machines for these operations have been widely acclaimed for their reliability, for their ease of adjustment, and for their ability to reduce scrap losses.

▲ SPOOLING MACHINE

This unit neatly winds extruded strips such as shoe welting, lacing, tubing, and strip gaskets onto spools. The standard model handles a 12" diameter spool, 12" wide. Adjustable traverse for different width extrusions insures even winding. Diameter build-up is compensated for by dancer rolls which maintain constant linear winding speed and uniform tension. The drive has a speed range from 20 to 1.

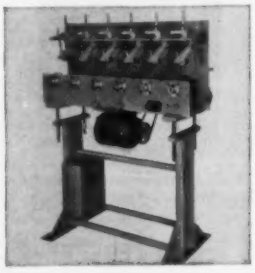


▲ AUTOMATIC BATCHER

Just load the magazine of the Progressive Automatic Batcher with cardboard tubes and set the desired number of yards per tube on the ocntrols. Then, without requiring additional attention, other than the replenishment of the tube supply, the Automatic Batcher will wind the proper yardage, cut off the film and start winding on a new tube!

▲ ANTI-WRINKLE SLAT EXPANDER

Smoothes out plastic film and fabrics during continuous roll operations. Expander slats move outward from center, pressing out any creases or wrinkles in the web. Permits operation of processing machinery at higher speeds. Delivers tight, neat rolls, improves printing register, cuts reject losses.



FASTER COLOR MIXING AT THE EXTRUDER ▼

Progressive has developed a new mixing method for extruders who want fast color changeovers with minimum waste material and minimum downtime. This method eliminates the necessity for stopping the extruder for cleaning, or for making any alterations in the extruder set-up.

The Progressive color mixer fits the hopper of any extruder. It feeds and mixes neutral dry-blend powder and carefully measured portions of color chips. The delivery of the unit is matched to the extrusion rate. *Full details on this cost-reducing device are available on request.*

RIGID PIPE PULL-OFF ▶

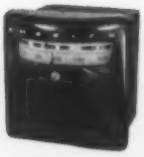
This machine pulls pipe from the diet at a uniform rate. Six paired rubber covered pull rolls and adjustable spring-loaded hold down rolls distribute tension over a length of pipe. The hold down rolls have quick toggle release for starting the pipe. The standard unit accommodates up to 8" O. D.; the roll assembly is adjustable for various other diameters. A 20 to 1 speed range electronic drive powers the machine.

Progressive machine co., inc.

Specialists in Plastic Film Handling Equipment

198-202 East 25th Street — Paterson 4, N. J.

New England Sales Rep: Barrett & Breen Co., 80 Federal St., Boston 10, Mass.



Progressive also manufactures film takeups, cut-off reels and slitters, film rewinders, and other machines for plastics extrusion and film handling.

THE MARK OF QUALITY

BARBER COLMAN

Wheelco Instruments

In plastics . . . it's WHEELCO for the "extras" that really count

400 Series Capacitrols are available in six control forms

Full plug-in Wheelco design is demonstrated by removal of measuring system

Model 297 offers finest low-cost temperature control

Typical control center provides multi-zone heat control for molding machine

Here are three outstanding "extras" available to every user of Wheelco instruments throughout the plastics industry.

1. Advanced design features — plug-in components, flexibility of operation, use of standard components for easy maintenance, etc. — all combined in the most complete line of top-quality instruments available.

2. A nationwide, factory-trained sales and service engineering organization, working closely with machinery builders and users.

3. Training programs for instrument technicians and supervisors conducted regionally by broadly experienced Wheelco instrument engineers.

Throughout the plastics industry, instrument men and production executives agree that it pays to see Wheelco first whether you need a single instrument or a complete control center. Get more details by writing today for your copy of Bulletin F-6485, "Capacitrols for the Plastics Industry."

ULTRA-FINE TO GRANULAR MATERIALS

for the Plastics Industry

The MIKRO-PULVERIZER—
for granular or fine grinding

The MIKRO-ATOMIZER—
for ultra-fine grinding

These MIKRO-D units are engineered to improve molding compounds and synthetic resins by perfect blending, fine grinding or controlled granulation to uniform particle size. In addition, they assure excellent results in grinding scraps and flashings.

THE MIKRO-PULVERIZER—a dustless pulverizer for dry or liquid milling, granulating, fine grinding and blending . . . no fans, cyclones or separators. Recent developments make it even more efficient in handling of heat-sensitive materials. Bulletin 51A.

The MIKRO-ATOMIZER—a 3-functional mill that pulverizes, air-classifies and conveys material in one operation. Cool, highly compact, it eliminates air conveyor, bucket elevator and screw conveyor. It is a mechanical, screenless pulverizer for production of smooth, ultra-fine powders in the 1-25 micron range. Bulletin 51G.

Also—the new jet-action MIKRO-PULSAIRE Collector—for optimum dust recovery—lowest maintenance costs. And, the MIKRO-Collector, standard of the reverse jet-ring type dust collectors.

Do you know all the latest ways to cut your packaging costs?

Are you familiar with new developments in package design that stimulate retail sales?

Are you sure you're using the best kind of package to protect your product from damage?

If you had to answer "No" to any one of these questions, it's likely that you're unnecessarily losing money every business day.

Fortunately there's an easy way out: MODERN PACKAGING magazine! It's the world's most authoritative publication devoted exclusively to packaging problems and their solutions. It analyzes all of the newest developments in packaging—materials, machinery, design and production. It reports each of the latest ways to merchandise packaged products of all types, from frozen foods to monkey wrenches.

The cost of an annual thirteen-issue subscription—including the giant annual Encyclopedia Issue—is only $7.00 in the U.S., its possessions and Canada; $20 elsewhere. You can begin yours today simply by writing us on your business letterhead. We'll bill you later.

Industrial Magazine Service, Inc.
575 Madison Avenue New York 22, N. Y.

In this plant making plastic printing plates, each press *has its own Speedylectric steam boiler.* Each press is independent of the others, and each gets steam at the right temperature and pressure. There is no big boiler to waste power when only one or two presses are needed, and it takes only minutes to bring a press up to temperature for a rush order.

For every plastic molding operation, a Speedylectric steam generator is the ideal answer. Using the most economical method of generating steam electrically, its design eliminates low-water hazard and practically removes the need for attendance. Maintenance is nil, and there's no risk of fire or explosion. Sizes from 2 to 60 Bhp, 15 to 500 psi and higher. Requires 220, 440, or 550 v A.C. UL listed, ASME Code. For more information write Pantex Mfg. Corp., Box 660S, Pawtucket 8, R. I.

COLORFUL SEALING

newest advancement in HEAT SEALING

Cosmos electronic Heat Sealers With exclusive COSMO-CHROME USA PAT. NO. 2747646

• Performs any standard heat sealing operation. *In addition,* it seals different colored edges, and seals three dimensional appliques in several different colors in a single operation.
Has more working power than any other machine with the same rating.
That's why more than 90% of our customers who have been using heat sealing machines of other makes switched to Cosmos.

Ask for details and sealing samples.

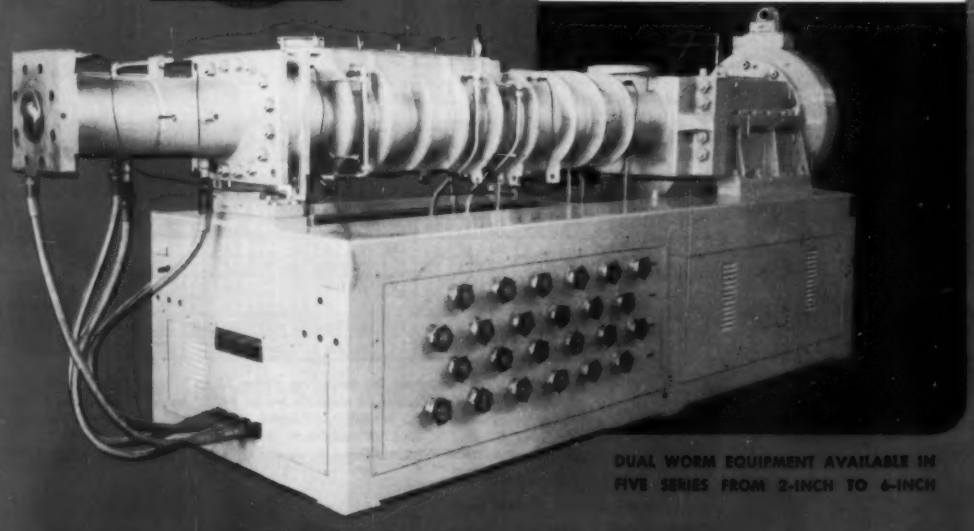
For Greater Processing Flexibility

Choose the WEI Compounder-Extractor-Extruder with the World's Greatest Leadership Experience

The guideposts for a successful future in the processing and manufacturing of plastics depends in a major part on the special abilities of the equipment your engineers choose. To be right up front with the ability to diagnose properly for handling—compounding, extruding—with or without extraction in both plastics and rubber, is the keystone of Welding Engineers' research and development in the service of the finest manufacturers in the world. For more than two decades, now, both management and production people, engineering and maintenance staffs have agreed that on ONE-OPERATION machinery . . .



The Dual Worm Design Makes The Big Difference

Standard equipment "prescribed" on a custom-fitted basis from hundreds of combinations of flight characteristics, various barrel lengths, several working sections and ingenious extraction openings as required . . . to the most substantial production rates . . . with minimum floor space and all-in-one-operation labor economies.

WEI Single Worm Production Extruders

Designed and manufactured to super-strength, increased output standards under the same strict and experienced engineering quality control always associated with W.E.I. Dual Worm compounder-extruders. Ideal for continuous operation processing of most important thermoplastics. Write for catalog No. 642.

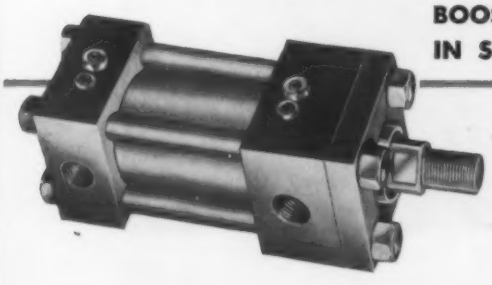
① "A" and "H" Models 82, 84 and 86 with strokes over 18" require stop tubes.

Column strength requires larger diameter piston rods for the following:



Air Cylinder Models A82, 84, and 86 with strokes inside area (1), when operated at 100 psi and over;

All hydraulic models with strokes inside area (2) and Models H82, 84, and 86 with strokes in area (4), when operated at 2000 psi and over;

Models H82, 84 and 86 with strokes inside area (3), when operated at 1000 psi and over.

Depending upon Trunnion Pin location, "A" and "H" Models 83 with standard diameter piston rods can have longer strokes than Models 82, 84 and 86.

See Miller File #251 for oversize piston rod and stop tube requirements.

BOOSTERS IN STOCK

Immediate Delivery on the following Miller 25 to 1 Ratio Boosters (80 psi air input produces 2000 psi hydraulic oil output): Model B4, 5" bore, 1" dia. ram, 6" and 12" strokes; Reciprocating Booster Model DA77-RBAB, 5" bore, 1" dia. ram, 6" stroke. Also Booster Tanks, 5" dia., 6" and 10" heights.

Slitter & Rewinder

MODEL 635

for FILM, FOIL, TAPE, PAPER

- **SHEAR CUT**
- **BURST CUT**
- **RAZOR BLADE**
- **SCORE CUT ***

In slitting plastic film, laminated foil, tape, glass cloth and paper, the model 635 utilizes the latest techniques and developments in the slitting and rewinding field.

The dual differential rewind, enables webs to be slit into four different widths of tape with individual tension controls for each width being rewound. The differential rewind principle produces high quality rewound rolls despite out of caliper mill rolls and materials, by allowing each rewound roll to slip with respect to its neighboring rolls and be wound up under its own controlled tension, thus reducing rejects and resulting in more economical production.

Change over from shear cut to razor blade or to burst, takes only a matter of minutes, giving complete versatility of slitting methods for handling a wide range of materials.

All tension controls on the unwind and rewind are air operated with gauges and regulators provided, to permit determination of optimum running conditions for a given material and to enable workers to repeat these settings without guess work. John Dusenbery Co., Inc., 274 Grove Ave., Verona, N. J., Tel: CEnter 9-3900.

**On special applications score cut can be provided.*

FELLOWS

Fastest Automatic Machines in Each Capacity Range!

In each of three capacity ranges, Fellows Injection Molding Machines are your key to extra profit through high-speed, reject-free, fully automatic operation.

Built-in controls make set-ups fast and relatively simple. Difficult industrial or defense jobs as well as mass-produced consumer pieces, in practically all moldable resins, are produced at lower cost per part on Fellows machines than on any others.

Get full information about Fellows Injection Molding Machines from your Fellows Plastic Specialist. Ask him, too, about the Fellows Plans for deferred payment. Just write, wire, or phone any Fellows office.

TREAT POLYETHYLENE FILM FOR PRINTING

at low cost ELECTRONICALLY

SAVE TIME!! SAVE MONEY!! the revolutionary AETNA electrode (patent pending) simplifies the treating of polyethylene film by bombarding the surface.

NO ADJUSTMENTS—Simply set the single knob remote control and this precision electrode treats film uniformly in any gauge, widths to 66 inches, in strips or overall.

NO DOUBLE-HANDLING—The AETNA amazing electronic treater can be conveniently mounted on any type of extruder to produce treated film in one simple operation.

NO MAINTENANCE PROBLEMS — No more daily servicing! Simply install this small, compact, low-cost unit wherever desired and forget about it.

NO BURN THROUGH—This scientifically precise method guarantees safe, sure results every time as part of actual printing or extruding operations.

For further information write or wire today.

Curtiss-Wright Coating Control System

Operator adjusts controller to proper specification for each order.

Insures "On Spec" Production for Federal Industries

Car upholstery of modern plastic boasts longer wear, brighter colors, a variety of grains and textures. Federal Industries division of Textron, Inc., Belleville, N. J., is a leading manufacturer of plastic coated upholstery fabric for the automotive industry. To maintain continuous quality and "on spec" production, Federal has installed a Curtiss-Wright Non-Contact Coating Control System for complete uniformity on every run.

This system monitors coated stock continuously. Any variation from proper weight or thickness specified for each order is caught by the nuclear transverse scanner and shown instantly on the target meter and chart recorder. Correction adjustments are simple and sure, scrap losses reduced, time and raw materials saved.

Whatever your type of plastic film, sheet or coated stock manufacturing operation, a Curtiss-Wright Non-Contact Coating Control System with custom-designed installation can effect savings and increase quality production. Write for complete details and application information.

LAKE ERIE Molding Presses

Standard and Custom-Built from 15 to 5000 tons

Lake Erie offers a complete line of compression, transfer, laminating and laboratory molding presses. The many designs include automatic, semi-automatic and manually operated models . . . multi-unit, self-contained and accumulator operated types. Presses manufactured by Lake Erie are noted for their sturdy construction, fast operation and reliable performance.

HIGH-TONNAGE PRESSES

Hydraulic presses with capacities up to 22,000 tons are manufactured by Lake Erie. This experience with heavy equipment enables Lake Erie to furnish big, high-tonnage presses of *tested design* to molders who need equipment capable of *producing efficiently* the giant-size moldings now being ordered by many customers.

STEAM PLATES . . . available in sizes up to 80" wide in any length desired.

A battery of SIX 113-Ton Hydraulic Presses with hydraulic pressure furnished by ONE pumping unit and ONE motor!

The hydraulic circuit is so designed that pressure is maintained in five presses while the sixth is opening or closing. Automatic cycle control of each press is by pushbutton and adjustable timer.

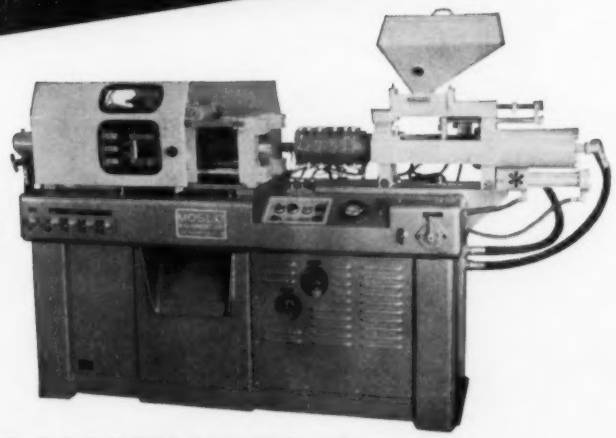
This system represents considerable reduction in initial and maintenance costs by eliminating the expensive, space-consuming accumulator while retaining its desirable features.

For full information, see our Representative or write us direct.

BUILDERS OF MACHINERY SINCE 1854

The Moslo DUPLIMATIC—2½ ounce machine designed for high speed production of cord plugs and insert molding. Molds all Thermo-Plastic materials.

MOSLO INJECTION PLASTIC MOLDING MACHINES



Out-produce other machines with TWICE the rated capacity

It may sound unbelievable, but it is a fact that Moslo injection molding machines turn out twice the production of similar competitive machines.

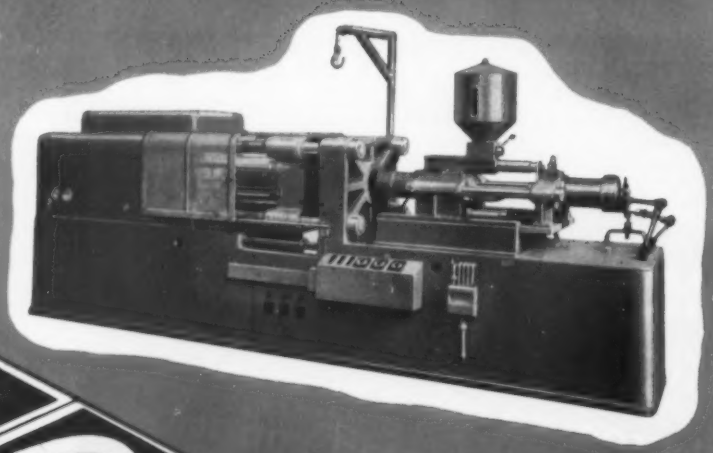
Moslo machines are equipped with the latest automatic controls and safety features, are ruggedly constructed for years of continuous running, and operate at speeds that make *production profitable.*

To appreciate fully how a Moslo machine can benefit you, write for complete specification material.

Better yet, make a visit to our headquarters and we will arrange a demonstration using your own molds.

The Moslo Model 74-7-2—2 ounce injection molding machine. **

The Moslo Model 75-8-4—4 ounce injection molding machine. **



*Hydraulic pull-back for plasticizing assembly is optional equipment on 2 ounce model and standard equipment on Model 75.

**2 and 4 ounce machines available with long stroke clamp for deep-draw work as optional equipment.

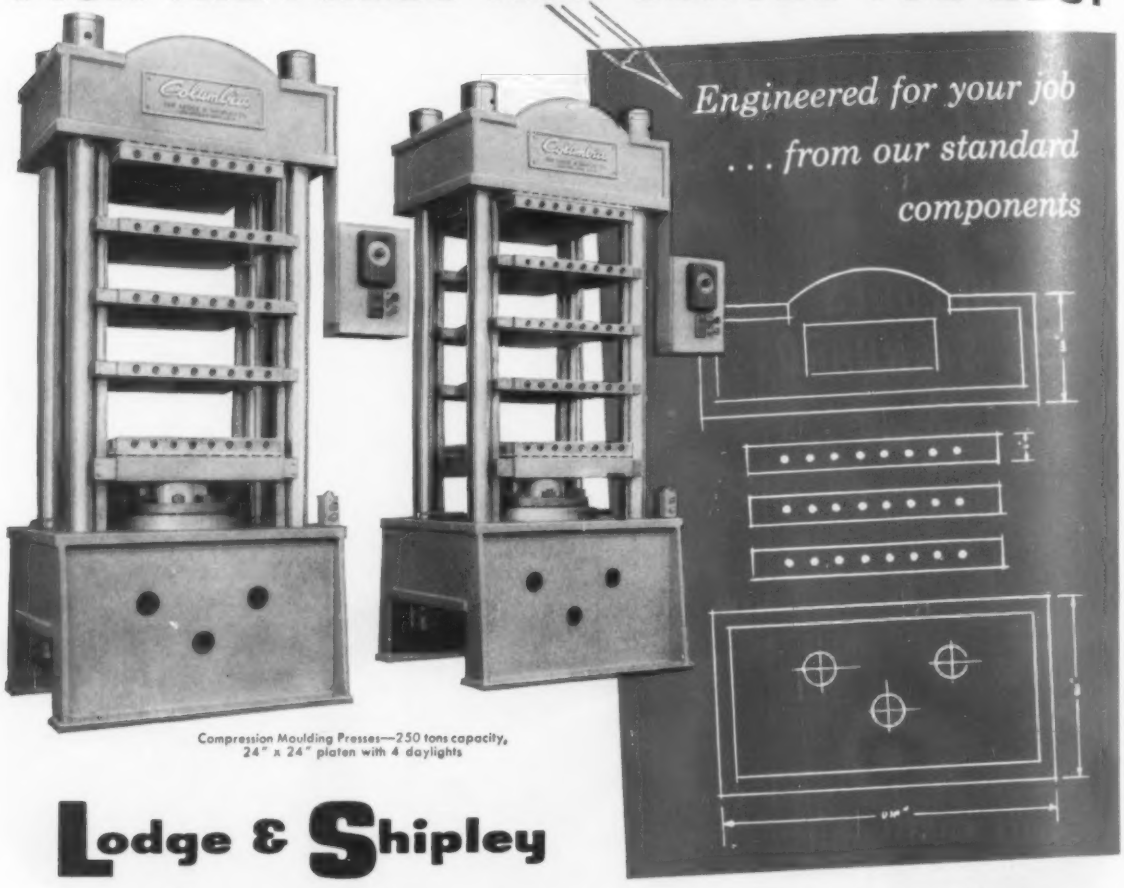
FOR GREATER PROFITS IN PRODUCTION MOLDING



The LEWIS pre-plasticizer scores two "firsts". (1) It was developed especially for an 8-ounce machine. (2) It is furnished as *standard equipment.*

A new concept in pre-plasticizer design, this unit gives molders unprecedented capacities and flexibility of operation. Because of its extremely precise temperature control, it permits intermittent operation without flashing or burning . . . can operate at greatly decreased injection pressures and temperatures. In fact, MODEL "6P" is the first machine capable of molding the new low-pressure linear-type polyethylenes as well as other materials.

The LEWIS "6P" is more than an "improved" model . . . *it is the most versatile production machine ever offered at competitive prices in the 8-ounce class.*

7360-LWM

PICK THE PRESS THAT SERVES YOU BEST

Compression Moulding Presses—250 tons capacity, 24" x 24" platen with 4 daylights

Lodge & Shipley

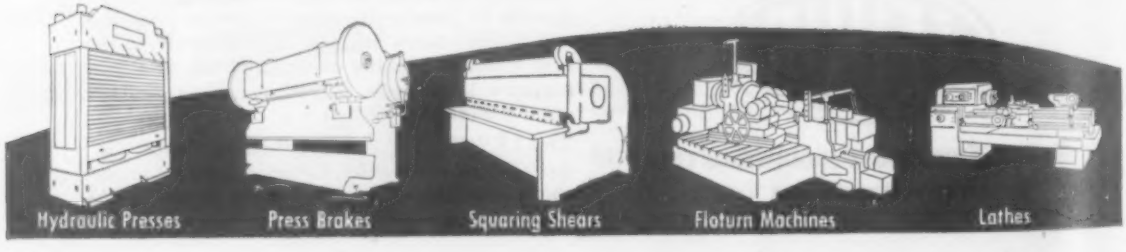
hydraulic compression moulding presses

Pick the press that will serve you best! Lodge & Shipley Hydraulic Compression Presses are job-proved for easy operation, high output, quality production and minimum maintenance. And the price is low!

Among outstanding features praised by users are:

TROUBLE-FREE HYDRAULIC SYSTEM . . . special welded fittings and seamless tubing

AUTOMATIC AIR-BLEEDING VALVE . . . eliminates dangerous manual bleeding task



UNITIZED PUMP . . . reservoir, pump, valves, gauges . . . all in one compact unit

CONVENIENT CONTROLS . . . handily mounted "open" and "close" push buttons

PRECISION CONSTRUCTION . . . for more production, fewer rejects

See for yourself . . . write for FREE Bulletin HP-14 with complete details:

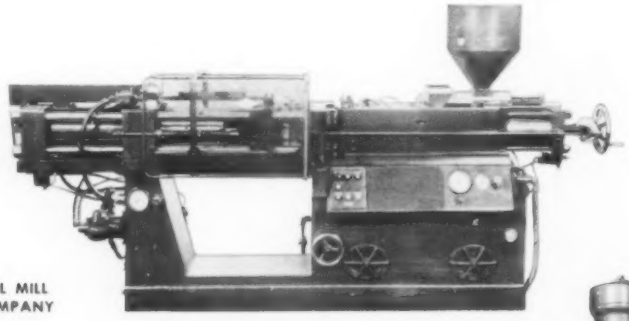
VICKERS® Hydraulic Controls

The modern plastic molding machines illustrated here are representative of the many that use Vickers hydraulic equipment. Vickers hydraulic pumps are ideally suited to this type of machinery, providing dependable service and economy of operation for a wide range of cycling speeds and tonnage requirements. In addition, Vickers valving, which is suitable for almost every pressure and control purpose, assures the unvarying control that means product uniformity. The fully automatic control provided speeds production and cuts costs.



Flexibility is another important characteristic of Vickers Hydraulic Controls. The control cycle on Vickers-equipped machines can be altered easily to accommodate changes in material characteristics and product requirements. Yet when established, the new control cycle is always followed precisely. Thus, a Vickers-equipped machine will provide the most economical production cycle for a wide variety of parts and conditions.

Vickers Hydraulic Controls can automatically protect the machine against excessive pressure due to mechanical failure or improper material characteristics—against mistakes and abuse.

Vickers Hydraulic Controls are important components of modern, high-production plastic molding equipment.

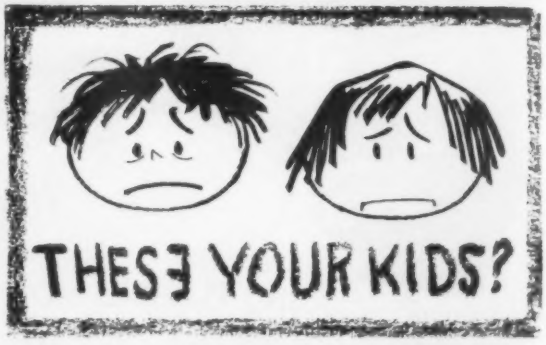
OFFERING THE EXPERIENCE OF 25 YEARS AND MORE THAN 3000 INSTALLATIONS

. . . They're Engineered for Your Specific Requirements

First we analyze your problem. Then we give you a "complete winding package" — tailor made to your needs — including motor, winder, stands and all other accessories.



We make 5 different types of winders for handling webs, sheets and single strands. One of them is surely adaptable to your needs.

Get more information. Write for the

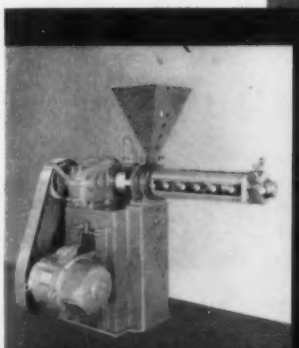
Xaloy

bimetallic heavy wall extruder cylinders

WORLD'S TOUGHEST...LONGEST LASTING LINERS AND BARRELS



Xaloy liners are fabricated to this broad range of design specifications

Xaloy bimetallic cylinders readily adapt to every extruder design—are manufactured to individual specifications.

Xaloy and Xaloy 306 have been developed with specific hardness and abrasion resistance properties to protect extruder cylinders from severe and destructive actions of thermoplastics and compounds used in plastics and rubber extrusions.

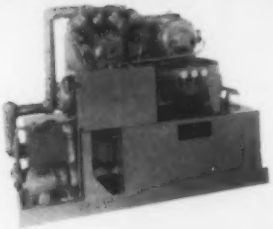
DIE SINKING — MOLD MAKING MACHINERY



Tracer-Controlled Gorton Pantographs, Die and Mold Duplicators and special machines constantly make important contributions to your industry. The illustration shows how an intaglio design is transferred from an enlarged master to the work piece for fast, low-cost production of a high-quality mold for the plastic cover of a silverware chest. This is one of many examples of special operations that make the Gorton Pantograph almost indispensable in many plastics plants.

Now ready for you: concrete evidence of Pantograph versatility — from tiny pieces on up.

MAYER **Has It!** COOLING EQUIPMENT DESIGNED FOR QUALITY CONTROL AND ECONOMY OF PLASTIC PROCESSING OPERATIONS

Chil-er Recirculating Units for . . .

Circulation of chilled process water for injection molds, extruders, cooling baths; printing rolls, embossing rolls, calandar and mill rolls.

Dip-Cooling Baths for . .

Instant chilling of molded plastic forms with heavy cross sections, to prevent 'sinks', distortion and warp. Completely self-contained, provides thermostatically-controlled temperatures to 38° F.

Water Economizers for . . .

Recirculation and cooling of process water where temperatures up to 85° F. are satisfactory.

Saves up to 95% of water cost.

Permits use of increased water volume.

SUPPLIES

For related editorial information see pp. 650, 818, 890.

ABRASIVE MATERIALS

- Acme Scientific Company, Chicago
- Carborundum Co., Niagara Falls, N. Y.
- Chemical Development Corp., Danvers, Mass.
- Composition Materials Co., Inc., New York
- Cratex Mfg. Company, San Francisco, Calif.
- Hewitt, C. B., & Bros, Inc., New York
- Kramer, H. W., Co., Inc., Richmond Hill, N. Y.
- Lacrinoid Products Ltd., Essex, England
- Lea Manufacturing Co., Waterbury, Conn.
- Loed Chemical Corp., York, Pa.
- Lupoline Automatic Polishing Equipment Corp., Tuckahoe, N. Y.
- Minnesota Mining & Mfg. Co., St. Paul, Minn.
- Norton Company, Worcester, Mass.
- Raybestos-Manhattan, Inc., Passaic, N. J.
- Scientific Abrasives, Chicago
- Sirotta, Bernard, Co., Brooklyn, N. Y.
- Sommer and Maca Glass Machinery Co., Chicago
- Tumb-L-Matic, Inc., St. Mary's St., Stamford, Conn.
- Vapor Blast Mfg. Co., Milwaukee, Wisc.
- Wagner, Charles A. Co., Phila., Pa.

BAGS, MULTIWALL PAPER

- Bemis Bros. Bag Company, St. Louis, Mo.
- Continental Can Co., Inc., Shellmar-Vetner Div., Mt. Vernon, Ohio
- Equitable Paper Bag Co., Inc., Long Island City, N. Y.
- Milprint, Inc., Milwaukee, Wisc.
- Owens-Illinois Glass Company, Toledo, Ohio

BAGS, VACUUM AND PRESSURE

- Blossom Mfg., Co., New York
- Continental Can Co, Inc., Shellmar-Betner Div., Mt. Vernon, Ohio
- Milprint, Inc. Milwaukee, Wisc.
- Shore Line Industries, Clinton, Conn.

BELTS, BANDS AND SPECIALTIES, ABRASIVE

- Cratex Mfg., Company, San Francisco, Calif.
- Sommer & Maca Glass Machinery Co., Chicago

BELTS, STAINLESS STEEL

- Metalsmiths Div., Orange Roller Bearing Co., Orange, N. J.
- Sandvik Steel, Inc., Fair Lawn, N. J.

BERYLLIUM FOR MOLDS

FASTENING DEVICES

(See also Screws)

Brush Nail Expansion Bolt Co., Greenwich, Conn.
Central Screw Company, Chicago
Hassall, John, Inc., Westbury, N. Y.
Palnut Company, Mountainside, N. J.
Paragon Plastic Corp., New York
Phelps Mfg., Co., Westport, Conn.
Tinnerman Products, Inc., Cleveland, Ohio

FLEXIBLE MATERIALS FOR MOLDS

Biggs, Carl H., Co., Inc., Los Angeles, Calif.
Chemical Development Corp., Danvers, Mass.
•Chemical Products Corp., E. Providence, R. I.
•General Tire & Rubber Co., Bolta Products Div., Lawrence, Mass.
Houghton Laboratories, Inc., Olean, N. Y.
Parcloid Chemical Co., Midland Park, N. J.
Ren Plastics Inc., Lansing, Mich.
•Reynolds Chemical Products Co., Ann Arbor, Mich.
Technicraft Co., Boston, Mass.
Tylene Plastics, Michigan City, Ind.

HINGES, SPECIALTY METAL

•Geissel Manufacturing Co., Inc., Hillside, N. J.

HOSE AND TUBING

(Flexible Metal)

Flexaust Company, New York
Orchard Industries, Inc., Hastings, Mich.
Packless Metal Hose, Inc., Mt. Vernon, N. Y.

INKS

(For Printing Plastics)

•Acromark Company, Elizabeth, N. J.
•Apex Machine Co., College Point, N. Y.
Bensing Bros., & Deeney, Phila., Pa.
California Ink Company, Inc., San Francisco, Calif.
•Chemical Products Corp., East Providence, R. I.
Entwistle Manufacturing Corp., Providence, R. I.
Garan Chemical Corp., Gardena, Calif.
International Marking Machine, New York
•Irwin, Jewell, & Vinson Co., Dayton, Ohio
Jamestown Finishes, Inc., Jamestown, N. Y.
Kellogg, M. W., Company, Jersey City, N. J.
•Krieger Color Chemical Co., Inc., Los Angeles, Calif.
•Logo, Inc., Chicago
Markem Machine Co., Keene, N. H.
Matthews, Jas. H., & Co., Pitts., Pa.
Palmer, Homer W., & Co., Chicago
•Schwartz Chemical Co., New York
•Stanley Chemical Co., East Berlin, Conn.
•Sun Chemical Corp., L. I. C., New York
Vansul Sales Co., Englewood, N. J.

INSERTS

Groov-Pin Corp., Ridgefield, N. J.
Industrial Engineering Service, South Easton, Mass.
Maplewood Companies, Livingston, N. J.
Paragon Plastic Corp., New York
Phelps Mfg., Co., Westport, Conn.

JOINTS

(Flexible-Ball, Pipe, Swivel, Revolving)

Barco Manufacturing Co., Barrington, Ill.
Chiksan Co., Brea, Calif.
Rotherm Engineering Co., Inc., Chicago
Stowe Mfg., Co., Binghamton, N. Y.

KNIVES

(For Granulators and Cutters)

• Taylor, Stiles & Co., Reigelsville, N. J.

LABELS, PRESSURE SENSITIVE

(Self-Adhesive, for Plastics)

Aacon Industries, Inc., New York
Allen Hollander Co., Inc., New York
Archer Label Co., Los Angeles, Calif.
Avery Adhesive Label Corp., Monrovia, Calif.
Ever Ready Label, Belleville, N. J.
Goodren Products Corp., Englewood, N. J.
• Hopp Plastics, New York
Labelon Tape Co., Inc., Rochester, N. Y.
Midwest Decalcomania Co., Chicago
Minnesota Mining & Mfg., Co., St. Paul, Minn.
Nas-Kay Industries, Phila., Pa.

LAMPS, INFRARED

(See also Drying Equipment)

Cleveland Process Co., Cleveland, Ohio
• Entoleter Division, Safety Industries Inc., New Haven, Conn.
• Fostoria Pressed Steel Corp., Fostoria, Ohio
North American Electric Lamp, St. Louis, Mo.

MASKING PAPER AND TAPE

Carborundum Co., Niagara Falls, N. Y.
Johns-Manville, New York
Minnesota Mining & Mfg., Co., St. Paul, Minn.
Permacel Tape Corp., New Brunswick, N. J.
Serwell Products Co., Cleveland, Ohio
Sorg Paper Company, Middletown, Ohio
Williamson Adhesives, Inc., Skokie, Ill.

MATERIAL HANDLING EQUIPMENT

(Except expendable)

Tote System, Inc., Beatrice, Neb.

MATERIALS FOR HOBS AND MOLDS

(Steel, Beryllium, Etc.)

Brush Beryllium Company, Cleveland, Ohio
•Cadillac Plastic & Chemical Co., Detroit, Mich.
Chemical Development Corp., Danvers, Mass.
Crucible Steel Co. of America, Pittsburgh, Pa.
Latrobe Steel Company, Latrobe, Pa.

MATERIALS, MOLD MAKING

•Bestwall Certain-teed Sales Corp. Ardmore, Pa.
Chemical Development Corp., Danvers, Mass.
Chemical Products Corp., East Prov., R. I.
Crucible Steel Co., of America, Pittsburgh, Pa.
Elastomer Chemical Corp., Newark, N. J.
Houghton Laboratories, Inc., Olean, N. Y.
•Newbury Industries, Inc., Newbury, Ohio
Plastic Enterprises, College Pt., N. Y.
Ren Plastics Inc., Lansing, Mich.
•Schwartz Chemical Co., Inc., New York
Scientific Abrasives, Chicago

MOLD CLEANING COMPOUNDS

Agrashell, Inc., Los Angeles, Calif.
Chemical Development Corp., Danvers, Mass.
Garan Chemical Corp., Gardena, Calif.
Merix Chemical Company, Chicago
Oakite Products, Inc., New York
Pennsylvania Refining Co., Cleveland, Ohio
Puritan Manufacturing Co., Waterbury, Conn.
Scientific Abrasives, Chicago
Sirotta, Bernard, Co., Brooklyn, N. Y.
•Synthetic Products Co., Cleveland, Ohio

MOLD RELEASE AGENTS

(Mold Lubricants)

•Advance Solvents & Chemical, Div. of Carlisle Chemical Works, Inc., New Brunswick, N. J.
Aries Laboratories, Inc., Long Island City, N. Y.
B. B. Chemical Co., Cambridge, Mass.
Baker Castor Oil Co., Bayonne, N. J.
•Barrett, Div. Allied Chemical & Dye Corp., New York
Biggs, Carl H., Co., Inc., L. A., Calif.
•Borco Chemicals, Inc., Chicago
•Carbide & Chemicals Co., Div. of Union Carbide Corp., New York
Chemical Development Corp., Danvers, Mass.
Dennis Chemical Co., St. Louis, Mo.
Dow Corning Corp., Midland, Mich.
•Du Pont, E. I. deNemours, & Co., Inc., Wilmington, Del.
Eveready Pressurized Products, Inc., Cleveland, Ohio
Flexcraft Industries, Newark, N. J.
Garan Chemical Corp., Gardena, Calif.
Glyco Products Co., Inc., New York
• Harwick Standard Chemical Co., Akron, Ohio
Houghton, E. F. & Co., Phila., Pa.

•Indicates Advertiser.

Houghton Laboratories, Inc., Olean, N. Y.
Industrial & Domestic Silicone Distributor, Reseda, Calif.
• Injection Molders Supply Co., Cleveland, Ohio
Johnson, S. C. & Son, Inc., Racine, Wisc.
Lami-Plast Products Co., Tampa, Florida
• Lago, Inc., Chicago
Mallinckrodt Chemical Works, St. Louis, Mo.
Merix Chemical Company, Chicago
Minnesota Mining & Mfg. Co., St. Paul, Minn.
Moldrite Products Co., Providence, R. I.
• Naugatuck Chemical, Div. of U. S. Rubber, Naugatuck, Conn.
• Plastic Molders Supply Co., Inc., Fanwood, N. J.
Plastics Associates, Pasadena, Calif.
• Polyplastex United, Inc., Union, N. J.
Price Driscoll, New York
Ren Plastics Inc., Lansing, Mich.
Reynolds Metals, Co., Plastics Div., Grottoes, Va.
Rezolin, Inc., Santa Monica, Calif.
• Schwartz Chemical Co., Inc., New York
• Semet-Solvay Petrochemical Div., Allied Chem. & Dye Corp., New York
Serwell Products Co., Cleveland, Ohio
Specialty Products Co., Jersey, N. J.
• Stanley Chemical Co., East Berlin, Conn.
• Synthetic Products Co., Cleveland, Ohio
Technicraft Co., Boston, Mass.
• Thoreson-McCosh, Inc., Detroit, Mich.
Tylene Plastics, Inc., Michigan City, Ind.

OIL, HEAT TRANSFER AND HYDRAULIC

• Carbide & Chemicals Co., Div. of Union Carbide Corp., New York
• Dow Chemical Co., Midland, Mich.
Dow Corning Corp., Midland, Mich.
Houghton, E. F. & Co., Phila., Pa.
Pennsylvania Refining Co., Cleveland, Ohio
Union Oil Co. of California, Los Angeles, Calif.

PACKING, HYDRAULIC

Garlock Packing Company, Palmyra, N. Y.
Houghton, E. F. & Co., Phila., Pa.
Johns-Manvill, New York
• M & N Modern Hyraulic Press, Clifton, N. J.
Parker Appliance Company, Cleveland, Ohio
Raybestos-Mahattan, Inc., Passaic, N. J.

PARTICLE BOARD

Weyerhaeuser Sales Co., St. Paul, Minn.
Wynnewood Products Co., Jacksonville, Texas

PARTITIONS, PACKAGING

Artmor Plastics Corp., Cumberland, Maryland
Cornell Paperboard Products Co., Milwaukee, Wisc.
Federal Container Corp., Minneapolis, Minn.
Hinde & Dauch, Sandusky, Ohio
River Raisin Paper Co., Monroe, Mich.
Wabash Box Co., Terre Haute, Ind.

PIPE JOINT COMPOUNDS

American Hard Rubber, New York
Atlas Mineral Products Company, Mertztown, Pa.
• Chemical Products Corp., East Prov., R. I.
Dennis Chemical Co., St. Louis, Mo.
Garlock Packing Co., Palmyra, N. Y.
Haveg Industries, Inc., Wilmington, Del.
Lake Chemical Co., Chicago
Parker Appliance Company, Cleveland, Ohio
• Reynolds Chemical Products Co., Ann Arbor, Mich.

PURGING COMPOUNDS

Amco Plastic Materials, Inc., Brooklyn, N. Y.
• American Molding Powder & Chemical Corp., Brooklyn, N. Y.
• Gering Products, Inc., Kenilworth, N. J.
• Injection Molders Supply Co., Cleveland, Ohio
Merix Chemical Company, Chicago
Multiplastics-Inc., Wallingford, Conn.
• Plastic Molders Supply Co., Inc., Fanwood, N. J.
• Semet-Solvay Petrochemical Div., Allied Chem. & Dye Corp., New York
Scientific Abrasives, Chicago
Wasco Products, Inc., Cambridge, Mass.

RELEASE PAPERS

American Combining Corp., Rockaway Beach, Queens, N. Y.
• Endura Corp., Quakertown, Pa.
• Mosinee Paper Mills Co., Mosinee, Wis.
Newark Paraffine & Parchment, Newark, N. J.
Paterson Parchment Paper Company, Bristol, Pa.
• Riegel Paper Corp., New York
Sorg Paper Company, Middletown, Ohio

ROLL LEAF

(Stamping Foil)

• Acromark Company, Elizabeth, N. J.
Admiral Coated Prods., Inc., Bklyn., N. Y.
• Apex Machine Co., College Point, N. Y.
• Gane Bros., & Lane, Inc., Chicago
• General Roll Leaf Mfg. Co., Elmhurst, L. I., N. Y.
Gravert, R. W., Inc., New York
Griffin, Campbell, Hayes, Walsh, Inc., New York
• Kingsley Stamping Machine Co., Hollywood, Calif.
Metallizing Products Co., Norwalk, Conn.
• Olsenmark Corp., New York
• Peerless Roll Leaf Co., Inc., Union City, N. J.
Reichel Paper Corp., New York
Swift, M. & Sons, Inc., Hartford, Conn.

ROLLERS, FOR ROLLER COATING

• Apex Machine Co., College Point, N. Y.
• Cylinder Mfg., Co., Hawthorne, N. J.
• Finish Engineering Co., Inc., Erie Pa.
Inta-Roto Machine Co., Richmond, Va.
Lembo Machine Works, Inc., Paterson, N. J.
• Roehlen Engraving Works, Inc., Rochester, N. Y.
Stowe-Woodward, Inc., Newton Upper Falls, Mass.

SAW BLADES

Disston, Henry Division, H. K. Porter Company, Inc., Phila., Pa.
Do All Company, Des Plaines, Ill.
• Forrest Mfg. Co., Rutherford, N. J.
• Lemmon & Snop, Grand Rapids, Mich.
Radical Cutter Manufacturing Corp., Elizabeth, N. J.
Simonds Saw & Steel Co., Fitchburg, Mass.

SCREWS

(Drive, Thread Cutting, Thread Forming)

Central Screw Company, Chicago
Electro-Chemical Products Corp., Cleveland, Ohio
Hassall, John Inc., Westbury, N. Y.
• Johnson Manufacturing Co., Chippewa, Wisc.
Paragon Plastic Corp., New York
• Parker-Kalon Div., General American Transportation Corp., Clifton, N. J.
Southern Screw Company, Statesville, N. Carolina

SCREWS EXTRUDER

• Davis-Standard, Div. of Franklin Research, Mystic, Conn.
Fabbrica Prodotti Thermoplasitici Carlo Pasquetti, Varese, Italy
• Killion Tool Mfg., Co., Verona, N. J.

SPRAY PAINTING FIXTURES

Binks Manufacturing Company, Chicago
• DeVilbiss Company, Toledo, Ohio
• Finish Engineering Co., Inc., Erie, Pa.
Fiore, Wm. H., Bklyn., N. Y.
Houghton Laboratories, Inc., Olean, N. Y.
Pareagon Plastic Corp., New York
Serwell Products Co., Cleveland, Ohio
W & A Co., Inc., Attleboro, Mass.

TAPS

Bath, John & Company, Inc., Worcester, Mass.
Bay State Tap & Die Company, Mansfield, Mass.
Hypro Tool Company, New Bedford, Mass.

TOOLS, CARBIDE TIPPED

Allegheny Ludlum Steel Corp., Pittsburgh, Pa.
• Forrest Mfg., Co., Rutherford, N. J.
• Kramer, H. W., Co., Inc., Rich. Hill, N. Y.
Maplewood Companies, Livingston, N. J.

• Indicates Advertiser.

Complete addresses of companies listed appear on pp. 1123–1149

TUBES, H. F. ELECTRONIC

Guild Electronics Inc., New York

TUMBLING MEDIA

(Pegs and Compounds)

Carborundum Co., Niagara Falls, N. Y.
•Chemical Products Corp., East Prov., R. I.
Cratex Mfg. Company, San Francisco, Calif.
Harrison & Company, Inc., Haverhill, Mass.
•Kramer, H. W., Co., Inc., Richmond Hill, N. Y.
Lacrinoid Products Ltd., Essex, England
Lea Manufacturing Co., Waterbury, Conn.
Lead Chemical Corp., York, Pa.
Lignum Chemical Works, L.I.C., N. Y.
•Lupoline Automatic Polishing Equipment Corp., Tuckahoe N. Y.
Minnesota Mining & Mfg., Co., St. Paul, Minn.
Merix Chemical Company, Chicago
Oakite Products, Inc., New York
Puritan Manufacturing Co., Waterbury, Conn.
Scientific Abrasives, Chicago
Sirotta, Bernard, Co., Brooklyn, N. Y.
Tumble-Buff Laboratories, Inc., Jamaica, N. J.
•Tumb-L-Matic, Inc., St. Mary's St., Stamford, Conn.

CONVERTERS AND PROCESSORS

The following personnel and equipment directories are designed to be as complete as possible on the basis of available information submitted by the companies themselves. Listings are alphabetical and geographical, by state.

CUSTOM MOLDERS AND EXTRUDERS

C—Compression; E—Extrusion; I—Injection; T—Transfer; CM—Cold Molding

ALABAMA

Decatur Plastic & Eng., Inc., Decatur (*I*)
Injection Machines: 4-3 oz.; 1-12 oz.; 1-16 oz.
Pres., Sls. Mgr. & Pur. Agt.—M. E. Hickson
Vice Pres.—John Sewell

ARIZONA

***Royal Mfg. Co., Inc.,** Prescott, (*I, E*)
Injection Machines: 1-4 oz.; 1-6 oz.; 3-8 oz.
Extrusion Machines: 1-2½"; 7-3½"; 2-4½"
Pres. & Sales Mgr.—C. C. Coates
V. Pres.—John D. Jackson & H. L. Berman
Pur. Agt.—E. C. Sturm

CALIFORNIA

***Alladin Plastics, Inc.,** Los Angeles (*I*)
Injection Machines: 8 oz.-4; 16 oz., 1; 12-16 oz., -1; 20-28 oz.-3; 2-3 oz.-1
Pres.—Sam Avedon
Vice Pres.—Hon. L. Taylor, Plant Supt.
Sales Mgr.—Nelson Trust
Pur. Agt.—Fred R. Berman

***American Molding Co.,** San Leandro ((*C, I, T, E*)
Compression Presses: 8
Injection Machines: 6 to 12 oz.
Transfer Presses: 3 to 150 tons
Extrusion Machines: 3 to 3½"
Pres.—W. D. Love, Jr.
Chief Eng.—John Robb
Sales Manager—Harry Peet
Pur. Agt.—E. B. Mellor

Art Plastics Mfg. Co., Los Angeles (*C, I, E*)
Compression Presses: 3
Injection Machines: 3
Pres.—R. R. Conell
Vice Pres.—Henry Conell
Sales Mgr.—Frank Brown

Automatic Plastic Molding Co., Berkeley (*C, T*)
Compression Presses: 1-15 ton; 1-150 ton; 1-250 ton
Injection Machines: 2-4-6; 2-8
Pres.—Forrest Engelhart
Vice Pres.—A. J. Carlson
Sales Mgr.—A. J. Carlson
Pur. Agt.—Forrest Barnes

***Chemtron Fiber Glass Co.,** El Monte (*CM*)
Pres.—R. L. Kinch
Vice Pres.—C. L. Kuchinsky
Sales Mgr.—J. C. Larcom
Pur. Agt.—A. R. Kinsley

***Collins, Caldwell & Dague, Paramount** (*E*)
Extrusion Machines: 4
Pres.—Wm. B. Collins
Vice Pres.—Lee M. Caldwell
Sales Mgr.—Harold F. Dague

Crest Molded Products, Inc., Arcadia (*C, T*)
Compression Presses: 2-40 ton; 6-150 ton; 2-200 ton; 2-300 ton
Transfer Presses: 2-40 ton; 2-80 ton; 4-150 ton, 2-200 ton
Pres.—Charles Marins
Vice Pres.—Stephen Civerolo
Sales Mgr. & Pur. Agt.—K. R. Mergen

Delkay Plastics Corp., Inglewood (*I*)
Injection Machines: 1-3 oz.; 3-6 oz.; 3-16 oz.
Owners: Edmond Favre & Jack Mersman

***Eldon Manufacturing Co.,** (*C, T*)
Compression Presses: 18-50 ton to 350 ton
Transfer Presses: 14-50 to 200 ton
Pres.—Robert Silverstein
Vice Pres.—Walter Burroughs
Sales Mgr & Gen. Mgr.—Darrel Francy
Pur. Agt.—Louis Berkowitz

***Gaylord Plastics, Inc.,** Santa Monica (*C, T*)
Compression Presses: 1-10 ton; 1-75 ton; 4-85 ton
Transfer Presses: 1-2 ton; 5-10 ton
Pres. & Sales Mgr.—G. W. Main
Vice Pres. & Pur. Agr.—H. P. Grimberg

***Gibbs Manufacturing Co.,** Berkeley (*C, I*)
Compression Presses: 10-30 to 300 tons
Injection Machines: 1-6 oz.; 1-12 oz.
Pres.—J. Gibbs

***Jet Specialties Co., Inc.,** Los Angeles (*I, E*)
Injection Machines: 6 oz.; 8 oz.; 16 oz.; 2 oz.
Extrusion Machines: 5-2½"; 1-1½"; 1-2"; 2-3½"
Pres. & Gen. Mgr.—Lloyd W. Johnson
Vice Pres. & Sales Mgr.—Gerald H. Johnson
Controller, Pur. Agt., & Ass't to Pres.—Malcolm S. Haywood

Kennerley-Spratling, Inc., Berkeley (*C, I, T*)
Compression Presses: 50 to 100 ton
Injection Machines: 3 to 16 oz.
Transfer Presses: 50 to 100 ton
Pres.—Fred L. Kennerley
Vice Pres.—J. H. Murphy
Secy. & Vice Pres.—Ernest N. Spratling
Treas.—R. W. Garrett

***Kralov Plastic Pipe Co., Inc.,** Los Angeles (*E*)
Extrusion Machines: 2-2½"; 1-3½"; 1-4½"
Pres.—Arthur Gow
Vice Pres.—Robert C. Raab
Sales Mgr.—Russell W. Johnson
Pur. Agt.—B. Priess

***Lynch Asbestos Co.,** Los Angeles (*E*)
Extrusion Machines: 2-(1-2½ & 1-4½)
Pres.—R. O. Lynch
Vice Pres.—J. C. Hontev
Pur. Agt.—C. Cruen

***Marken Plastic Corp.,** Los Anglees (*E*)
Extrusion Machines: 2-3½"; 1-2½"
Pres.—Andrew M. Martin
Vice Pres. & Gen. Mgr.—W. Aidney Aitken
Vice Pres. & Plant Supt.—Ralph Luck

***Modern Plastics Co.,** Los Angeles (*I*)
Injection Machines: 1-4 oz.; 1-8 oz.; 2-8 oz.; 1-12 oz., 3-16 oz.
Pres.—George W. Van Vorst
Vice Pres.—Kenneth F. Carraher
Sales Mgr. & Gen. Mgr.—Myron W. Plum
Pur. Agt.—Ethel S. Wilson

Monrovia Plastic Co., Inc., Monrovia (*I*)
Injection Machines: 2-12 oz.; 1-4 oz.
Pres.—Swanson
Vice Pres.—Adsen Melickian
Gen. Mgr. & Secy.—W. R. Swanson

***New Plastic Corp.,** Los Angeles (*I*)
Injection Machines: 5-16 oz.

***Olympic Plastics Co., Inc.,** Los Angeles (*C, I, T*)
Compression Presses: 12-75-300 tons
Injection Machines: 8-2 oz.-16 oz.
Transfer Presses: 4-50-250 tons
Pres.—David Rome
Vice Pres.—David C. Siteman
Sec., Treas. & Pur. Agt.—Harry Scott

***Peat Manufacturing Co.,** Norwalk (*I*)
Injection Machines: 1-16 oz.; 1-12 oz.; 3-8 oz.
Pres.—Roy L. Peat
Sales Mgr. & Pur. Agt.—C. O. Menig

* Operates own tool room.
● Indicates Advertiser.

Complete addresses of companies listed appear on pp. 1123-1149

*Plastic Age Sales, Inc., San Fernando (C, T)
Compression Presses: 1-450 ton, 48 x 80-48"; 1-110 ton, 14 x 120; 1-75 ton, 36 x 48; 10-12 x 24-48, 35 tons; 3-12 12-48", 35 ton; 1-36-48-45 ton.
Transfer Presses: 1-12 x 12-75 ton, 1-12 x 24-75 ton
Pres.—J. A. Dramer
Sales Mgr.—H. E. Renner
Pur. Agt.—Adolph Kramer

*Plastic Process Company, Division of Monadnock Mills, Los Angeles (E)
Extrusion Machines: 7-2½" to 4½"
Pres.—E. E. Kotkin
Vice Pres.—H. H. Wenk & H. R. Hedstron
Pur. Agt.—Mark Kotkin

Plastron Specialties, Inc., Los Angeles, (E)
Extrusion Machines: 1-1"; 2-2½"; 1-3½"

*Randazzo Plastic Co., Los Angeles (I)
Injection Machines: 5-3-8 oz.: One-4 oz.; One-12 oz.
Partner: Marco G. Randazzo
Partner: Marion G. Randazzo
Partner: Gus Rizzo

*Reinhold Engineering & Plastics Co., Norwalk (C, I, T)
Compression Presses: 8-100 ton, 4-200 ton; 2-250 ton; 2-300 ton; 3-400 ton; 2-750 ton
Injection Machines: 3-4 oz.
Transfer Presses: 3
Pres.—James P. Gruettner
V. Pres. Administration—H. J. Harris
Sales Mgr.—William H. Barner
Pur. Agt.—H. J. Harris

*Reinhold-Geiger Plastics, Inc., Los Angeles, (C, I, T)
Compression Presses: 39-100 to 4000 ton
Injection Machines: 7-1 to 3 oz.
Transfer Presses: 11-100 ton
Pres.—Lisle Reinhold
V. Pres.—Harry Geiger
Manager—Edgar A. Wanczuk

*Resinite Department, The Borden Co., Santa Barbara (E)
Extrusion Machines: 10 machines, various sizes
Gen. Mgr.—Grant Erlich
Sales Mgr. Industrial Production—Howard G. Smith
Sales Mgr. Consumer Goods—William Sedar

*Revell Industrial Division, Venice (I)
Injection Machines: 15-2 oz. to 12 oz.
Pres.—Lewis H. Glaser
Sales Engineer—Bernard Diggins
Pur. Agt.—Oliver Kimball

*Roger Mfg. Co., Oakland (C, I)
Compression Presses: 1-30 ton; 1-40 ton; 1-75 ton
Injection Machines: 1-4 oz.; 1-8 oz.; 1-16 oz.
Pres. and Owner—A. J. Roger

● Sierra Electric Corp., Gardena (C, I, T)
Compression Presses: 45-100 to 600 ton
Injection Machines: 2-4 to 8 oz.
Transfer Presses: 20-50 to 500 ton
Pres. & Sales Mgr.—L. T. Bordner
V. Pres.—R. R. Turner
Pur. Agt.—Lon Landry

*Westland Plastics, Inc., Los Angeles (I)
Injection Machines: 1-2 oz.; 1-9 oz.; 4-12 oz.; 1-16 oz.
Pres.—Fred Forsman
V. Pres.—Russel Forsman
Sales Mgr.—Bert Murman
Pur Agt.—Gus Forsman

*Wilcox Plastics, Inc., Montebello (C, I, T)
Compression Presses: 15-50 to 300 ton; 8-15 to 40 ton
Injection Machines: 3-6 oz.
Transfer Presses: 7-50 to 200 ton
Pres.—Frank Wilcox
V. Pres.—Chas. L. Nichols
Sales Mgr. B. H. Enos
Pur. Agt.—E. N. Huling

*Windman Brothers, Los Angeles (C, I)
Compression Presses: 20-75-400 ton
Injection Machines: 12-4 oz.-12 oz.
Pres.—Philip Windman (Partner)
V. Pres.—Sam & Murray Windman (Partner)
Sales Mgr.—Irving Windman (Partner)
Pur. Agt.—Oscar Windman (Partner)
Pur. Agt.—Fred Windman (Partner)

COLORADO

*Chaney Plastic Molding Co., Denver (I)
Injection Machines: 2-9 oz.; 2-6 oz.; 1-2 oz.
Pres., Sales Mgr. & Pur. Agt.—J. E. Chaney

*Denver Plastics, Inc., Golden (C, I)
Compression Presses: 1
Injection Machines: 4
Pres.—R. L. Millard
Sales Mgr.—H. F. Kusserow
Pur. Agt.—C. A. Gates

Ingwesen Manufacturing Co., Inc., Denver (I)
Injection Machines: 1-4 oz.; 2-8 oz.; 1-16 oz.
Pres. Sales Mgr.—T. E. Taplin
Vice Pres. & Pur. Agt.—M. B. Hecox

*Pikes Peak Plastics, Inc., Colorado Springs (C, I)
Compression Presses: 2-20 ton
Injection Machines: 2-1-4 oz.; 1-1 oz.
Pres.—Egon W. G. Wieselmann
Vice Pres.—Florence E. Wieselmann

*Reinhardt Plastics Company, Denver (C, I, T)
Compression Presses: 2-35T; 1-125 ton
Injection Machines: 1-1 oz.; 2-2 oz.; 1-4 oz.
Transfer Presses: 1-35T

*V. F. Rogers Plastic Molding, Denver (C, I, T)
Compression Presses: Three-18 ton, One 50 ton
Injection Machines: One 1 oz.
Transfer Presses: One-50 ton
Owner: V. F. Rogers

Yorker and Sons, Inc., Denver (I)
Injection Machines: 1-12 oz.; 1-8 oz.; 1-4 oz.; 2-2 oz.
Pres. & Pur. Agt.—Oscar B. Yorker
V. Pres.—Scott A. Gale
Gen. Mgr. & Sales Mgr.—Jack R. Peckman

CONNECTICUT

Atlantic Plastics, Inc., Stanford (I)
Injection Machines: 6-12 oz.; 2-4 oz.; 4-2 oz.
Pres.—Joseph E. Benoit
Vice Pres.—Neil S. Waterman
Treas.—William F. Sanford

●Bridgeport Molded Products, Inc., Fairfield, Conn. (C, I)
Compression Presses: 452 ton; 13-150 ton; 10-100 ton; 31-50 ton; 3-15 ton; 1-314 ton; 5-300 ton; 4-200 ton.
Injection Machines: 1-200 oz.; 1-28 oz.; 6-8 oz.; 1-60 oz.; 2-16 oz.; 2-6 oz.; 1-48 oz.; 1-22 oz.; 3-4 oz.; 1-32 oz.; 6-12 oz.; 3-2 oz.
Pres. & Sales Mgr.—L. P. Clark
Vice Pres.—E. A. Tyler
Pur. Agt.—E. Dattalo

Bridgeport Plastics & Rubber Co., Inc., Bridgeport (I)
Injection Machines: 2 1-4 oz.; 1-6 oz.
Pres. Sales Mgr. & Pur. Agt.—H. E. Cosselin
Vice Pres.—Frank R. Cosselin

●Butterfield, T. F., Inc., Naugatuck (C, I, T)
Compression Presses: 40-100 to 150 ton
Injection Machines: 7-202 to 80 oz.
Transfer Presses: 10-150 ton

*Colt's Plastics Co., Inc., Hartford (C, I)
Compression Presses: 8-100 ton; 42-80 ton; 12-40 ton; 4-80 ton
Injection Machines: 1-1½ oz.; 1-6 oz.; 4-8 oz.; 1-12 oz.
Pres.—Ernest Stroheim
Vice Pres.—W. C. Bentley
Sales Mgr.—Gregory J. Azarian
Pur. Agt.—L. F. Trouton

●*Connecticut Plastic Products Co., Inc., Waterbury (I, CM)
Injection Machines: 12-2 oz. to 16 oz.
Pres.—M. J. Kelly
V. Pres.—H. F. Reichenbuck
Sls. Mgr.—H. F. Reichenbuck
Pur. Agt.—M. F. Sullivan

●*Danielson Manufacturing Co., Danielson (I, E)
Injection Machines: 3-12 oz.; 6-4 oz.; 2-8 oz.; 2-1 oz.; 1-½ oz.; 1-5 oz.
Extrusion Machines: 2-1¼"; 1-2¼ in.; 1-3½ in.
Pres.—J. E. Holt
Vice Pres. & Sales—W. H. Chadbourne

Leathertone, Inc. Boston (*1, A, B*)
Max. size laminated sheet: 24 x 54" also continuous rolls
Specialize in: decorative laminates (flexible and rigid thermoplastics) for handbags-eye glasses-etc. industrial laminates for defense and research
Personnel: see p. 1106

North East Laminates, Inc. Methuen. (*4, A, B*)
Max. size laminated sheet: 49" x 144"
Specialize in: vinyl to metal, vinyl to hard board
Pres.—Joseph A. Leone, Jr.
Exec. V. Pres.—Robert S. Kesler
Sales Mgr.—Charles A. Wustlich
Pur. Agt.—Robert S. Kesler

● **Parkwood Laminates, Inc.** Wakefield (*1 A, B*)
Max. size laminated sheet: 36 x 120
Pres. & Sales Mgr.—Sherman R. Thayer
V. Pres.—Paul B. Leverette
Pur. Agt.—Vivian Aston

Pine-Wood Plastic Co. Inc. Cambridge (*1, B*)
Max. size laminated sheet: 48 x 96
Specialize in: decorative plastic on plywood resin bonded hot pressed panels, tops.
Pres. & Sales Mgr.—Harry L. Wood
Pur. Agt.—G. Howkins

Plastic Industrial Products, Inc. Somerville
Specialize in: vinyl and polyethylene shapes
Gen. Mgr.—John E. Beaumont
Pur. Agt.—I. M. Paridon

Reiss Associates, Inc. Lowell (*1, B*)
Max. size laminated sheet: 48 x 120, 30 x 144
Pres.—Ernest Reiss
V. Pres.—Alfred M. Reiss
Sales Mgr.—Roger G. Landers
Pur. Agt.—Arthur C. Carnes

● **Sandman, Eli, Co.** Worcester
Specialize in: impregnating and coating on fiberglass cloth and also vinyl impregnated fiberglass screen.
Personnel: see p. 1106

Springfield Moulders, Inc. Monson
Specialize in: industrial molding and short-runs
Pres.—Victor E. Rosenlund
V. Pres.—Gilbert E. Stacy

Trimount Plastic Co. Inc. Arlington (*1, 4, A, B*)
Max. size laminated sheet: 54 x 112
Specialize in: epoxy, decorative rigid and flexible laminates; convertible rear window flexible AS-6
Pres.—Arthur S. Braverman
Treas.—Seymour A. Buchine
Sales Mgr.—Edward Thorp
Pur. Agt.—Arthur S. Braverman and Edward Thorp

MICHIGAN

Acme Laminating & Plastics Co. Detroit (*4, A, B*)
Max. size laminated sheet 24" x 24"
Personnel: see p. 1103

Bangor Plastics, Inc. Bangor, (*2*) (*A*)
Specialize in: industrial casters and timing gears. High impact material
Pres.—Victor Miller
V. Pres. & Treas.—E. O. Wokeck
Sales Mgr.—E. O. Wokeck
Pur. Agt. & Secy.—G. F. Wokeck

●**Cadillac Plastic & Chemical Co.** Detroit (*1, 4, A*)
Max. size laminated sheet: 54" x 80"
Specialize in: laminating flexible vinyl sheeting
Pres.—Robert B. Jacob
V. Pres.—Richard J. Jacob
Sales Mgr.—Lloyd R. Marentette
Pur. Agt.—Frank Barnard

● **Detroit Macoid Corp.** Detroit (*2, 3*)
Max. size laminated sheet: 48" x 96"
Pres.—G. S. Hendrie, Sr.
V. Pres. & Treas.—J. E. Gould
Sales Mgr.—J. E. Gould
Pur. Agt. & Secy.—S. D. Bradley

Duralastic Products Co. Detroit (*A, B*)
Max. size laminated sheet 3 x 6
Personnel: see p. 1080

● **Fabricon Products—Div. Eagle Picher,** River-Rouge (*1, B*)
Max. size laminated sheet: 4' x 10'
Pres.—L. A. Fisher
Ass't. to the Pres.—C. L. Keller
Sales Managers—J. T. Galvin, Molded Div., R. C. Fontham, Plastics Impregnating Div., C. E. Feltner, Palinated Plastics
Pur. Agt.—J. E. Steiner

Horstil Industries Company, St. Clair Shore (*2, A*)
Max. size rolled tubing: 12"
Standard length tubing: 44" to 96"
Specialize in: rolled round & square tubing for tooling, coil forms and ducting.
Pres. & Pur. Agt.—H. H. Stilson, Jr.
V. Pres. & Sls. Mgr.—A. A. Stilson

Haskelite Mfg. Corp. Grand Rapids (*3, A*)
Max. size laminated sheet: 48 x 144
Pres.—A. N. Williams
V. Pres. in charge of sales—E. W. Stoner
Sls. Mgr.—B. J. Werk
Pur. Agt.—F. W. Mitchell

Reynolds Plastics, Inc. Walled Lake
Specialize in: experimental & model work
Pres.—George Kovacs
V. Pres.—H. B. Ben, J. A. Soltis
Sales Mgr.—H. B. Ben
Pur. Agt.—R. Wallet

Zenith Plastics Co. Ypsilanti
Specialize in: vacuum forming
Personnel: see p. 1104

MINNESOTA

Mayon Plastics, Hopkins
Specialize in: vinyl food & industrial hose from .25" to 2½" I. D. flexible clear and colored.
Partners—C. B. Thomes, R. D. Johnson, M. C. Nelson, M. Standish.
Gen. Mgr., Sls. Mgr. & Pur. Agt.—R. D. Johnson

Perma Seal Plastic Products Co. St. Paul (*4*)
Max. size laminated sheet: 12" x 18"
Pres.—Ralph H. Oby

MISSOURI

Hanley Plastics Company, St. Louis (*4, B*)
Max. size laminated sheet: laboratory 10" x 8"
Specialize in: hand layups, models, plastic moulds, jigs, and fixtures, and in new product development in these thermosetting materials. Consulting and research

George A. Kelley, Fredericktown
Max. size rolled tubing: extruded tube 1/16"-8" dia.
Max. size molded tubing: shapes to 4" width rods from 1/16"-up
Standard length tubing: to customer specification
Specialize in: close tolerance tubular & shape parts—small experimental runs —production runs
Owner—George A. Kelley

● **National Plastic Product Co.,** Odenton (*1, B*)
Max. size laminated sheet: 4' x 10'
Pres.—E. Winer
V. Pres.—A. Winer
Sales Mgr.—J. R. Brown
Pur. Agt.—D. J. Anderson

NEBRASKA

Kerr, R. W. Plastic Co. Hastings (*1, 2, 4, A, B*)
Pres.—R. W. Kerr
V. Pres.—Charlotte Kerr

Kerrco Products, Lincoln (*1, 2, 4, A, B*)
Max. size laminated sheet: 32" x 44"
Pres.—R. W. Kerr
Sls. Mgr.—D. W. Kemphill

NEW HAMPSHIRE

Keller Products, Inc. Manchester (*2, 3, 4, A, B*)
Pres.—Robert R. Keller
V. Pres.—John C. Stanhope
Sales Mgr.—James Ellet

NEW JERSEY

Carpenter, L. E. & Co. Wharton (*4, B*)
Personnel: see p. 1098

● **Davis, Joseph Plastics Co.** Arlington, (*1, 4, A, B*)
Max. size laminated sheet: 22" x 52"
Personnel: see p. 1082

● **Emeloid Co. Inc.** Hillside (*4, A, B*)
Max. size laminated sheet: 21 x 25
Pres.—M. P. Leeds
V. Pres.—J. S. Freundlich
Sales Mgr.—G. W. Emerson
Pur. Agt.—Mrs. Florence Headley

Glassoloid Corp. of America, Clifton (*4*)
Max. size laminated sheet: 24" x 52, 30 x 40"
Specialize in: flat bed laminators-decorative coating, vacuum forming
Pres.—Walter A. Roembke
V. Pres.—W. A. Frazier
Sls. Mgr.—Jim Campbell, Jr.
Pur. Agt.—R. S. Thurston

Gomar Mfg. Co. Inc. Linden (*4, A, B*)
Max. size laminated sheet 54"

Hydrawlik, Roselle
Max. size molded tubing: 2" diameter
Specialize in: (A) tubing, (B) sealed end container tubes
Pres.—George A. Brown, Sr.
V. Pres.—Robert C. Brown
Sls. Mgr.—George A. Brown
Pur. Agt.—M. M. Johnson

Plastex Process Co. Maywood (*4, A*)
Specialize in: laminating nylon film to webs of material up to 4" width.

Plastic Laminating Corp. Vaux Hall, (*4, A, B*)
Max. size laminated sheet: 38 x 48, 24 x 54
Specialize in: thermoplastic laminations, planishing, plastic materials for laminating-placo laminating presses.
Pres. & Sales Mgr.—Joseph Di Bella
V. Pres.—Vincent T. Cooney
Pur. Agt.—Terry Kane

● **Polyplastex United, Inc.** Union (*1, 4, A, B*)
Max. size laminated sheet: 48" x 96"
Personnel: see p. 1106

Ridge Printing Co. Inc. Ridgefield (*4*)
Specialize in: lamination of vinyl to vinyl, paper cotton & flannel, knitback matl., non-woven fab. and mylar
Pres. & Pur. Agt.—George M. Cohan

Rondale Company, Inc. Roselle (*4, A, B*)
Max. size rolled tubing: 56" width
Specialize in: continuous laminating 24" to 56" wide—6 gauge to 60 gauge thickness cloth, paper flexible vinyl film and vinyl sheeting, flexible embossed vinyls, expanded plastics.
Pres.—J. Rubin
V. Pres.—A. Eddy
Sales Mgr. & Pur. Agt.—S. Rubin

Spiral Glas Pipe Co. New Brunswick
Max. size tubing: 5" Have machine capacity for 6" but no tools
Standard length tubing: 20'
Specialize in: high pressure chemical resistant piping.
Pres.—Carl de Ganahl
Sls. Mgr.—C. Brice de Ganahl
Pur. Agt.—Amy Mackenzie

NEW YORK

Anorgana G. M. G. H., New York
Max. size rolled tubing: 500 mm dia.
Specialize in: unplasticized P. V. C. film, sheet tubing

Armen, Inc., Long Island City, (*2, 4*)
Max. size laminated sheet: 38½" x 54"
Specialize in: fluorocarbons
Pres.—Armen Garabedian
V. Pres.—Edward F. Wiseman
Pur. Agt.—Roland Perry

● **Busada Mfg. Corp.,** Maspeth,
Max. size molding tubing: 9" O. D.
Standard length tubing: 6 ft. & 20 ft.
Specialize in: transparent butyrate tubing & pipe
Pres. & Sales Mgr.—John K. Busada
V. Pres.—V. A. Busada

Du Verre, Inc., Buffalo (*2*)
Max. size molded tubing: 84" x 1, D.
Standard length tubing: 6'-0"
Specialize in: duct systems, hoods, stacks, fans, tanks, other special shapes
Pres.—J. R. Kelly
Sales Mgr.—T. F. Killeen
Pur. Agt.—Henry Hasbrouck

Glasply Corp., Mount Vernon (*2*)
Max. size rolled tubing: (Low Pressure) 48" Dia.
Standard length tubing: 20 ft. Max.
Pres., V. Pres., Sls. Mgr. & Pur. Agt.—Frank A. Lambert

Glass Laboratories, Inc., Brooklyn (*B*)
Specialize in: decorative trim
Pres.—Abraham Shanok
V. Pres. & Sls. Mgr.—Jesse P. Shanok
Pur. Agt.—Victor Shanok

● **Hopp Plastics,** New York (*1, 4*)
Max. size laminated sheet: 23 x 36
Pres.—Hermann Hopp
V. Pres.—Philip Hopp
Sales Mgr. & Pur. Agt.—George Hopp

Ideal Gold Stamping Co., New York (*B*)

Identification Service Corp., New York (*1*)
Max. size laminated sheet: 20" x 50"
Pres. & Pur. Agt.—H. G. Schonzeit
V. Pres. & Sls. Mgr.—J. H. Schonzeit

● Indicates Advertiser.

Lewis, J. P. Co., Beaver Falls (*1, A*)
Max. size laminated sheet: 40" x 60"
Specialize in: low cost electrical grade laminates
Pres.—James P. Lewis
V. Pres.—E. S. Nuspliger
Gen. Mgr.—J. C. Parsell
Pur. Agt.—F. C. Pressaw

Marbak, Inc., Brooklyn (*4, A*)
Personnel: see p. 1106

Murray Plastics Company, Poughkeepsie (*A*)
Max. size rolled tubing: 6" I. D.
Max. size molded tubing: 7/8" O. D.
Standard length tubing: 40"; 46"; 60"
Pres.—A. Murray

Pathway Plastic Corp., Mt. Vernon (*1, 4, A, B*)
Max. size laminated sheet: 16" x 20"
Specialize in: laminating acrylics
Pres., Sales Mgr. and Pur. Agt.—Martin Fox
V. Pres.— Ludwig Geist

Plastic Center, Rochester (*1, 4*)
Max. size laminated sheet: 12 x 12
Specialize in: laminated photos, cards display pcs. & documents
Pres. & Sales Mgr.—G. Dudly Ward
V. Pres. & Pur. Agt.—John W. Proctor

Printloid Plastics, Inc., New York (*1, 4, A*)
Max. size laminated sheet: 20 x 24
Pres.—G. Martin
V. Pres.—M. Martin
Sales Mgr.—J. M. Wodiska
Pur. Agt.—Miss A. Minner

●**Rubber Corp. of America,** Hicksville (*4, A, B*)
Max. size laminated sheet: 24" x 52"
Personnel: see p. 1106

Rudd Plastic Fabrics Corp., Brooklyn (*4, A, B*)
Max. size laminated sheet: 54" x 24"
Personnel: see p. 1106

Shoe Form Co., Inc. Auburn (*1*)
Max. size laminated sheet: 20" x 50"
Pres.—Frank P. DeWitt
Sales Mgr.—Gordon N. Tutton
Pur. Agt.—David E. Gregory

Sommers Plastic Products Co., New York (*B*)
Max. size laminated sheet: 25 x 54
Specialize in: decorative laminations
Personnel: see p. 1106

Spaulding Fibre Company, Inc., Tonawanda (*1, A*)
Max. size laminated sheet: 41" x 49"
Max. size rolled tubing: 6"
Standard length tubing 37"
Specialize in: vulcanized fibre, industrial laminates.
Pres.—C. C. Steck
V. Pres.—E. C. Knobloch
Pur. Agt.—A. P. Hardleben

Superior Laminating Co., New York (*4*)
Max. size laminated sheet: 5" x 8"
Specialize in: laminating medals, coins, insignia, etc.
Owner, Sales Mgr., & Pur. Agt.—Edward Rosner

Virginia Plak Co., New York (*4*)
Max. size laminated sheet: 35" x 38"
Specialize in: vinyls
Pres.—Edward A. Rosenberg
Sales Mgr.—Sydney N. Weis

OHIO

●**American Agile Corporation,** Maple Heights, (*1, 4*)
Specialize in: Custom Fabrications Extrusion, molding
Personnel: see p. 1085

Barron, J. E. Plastics, Inc., Cincinnati (*4, A, B*)
Max. Size Lam. Sheet 20 x 24.
Max. Size molded tubing: 18"
Standard length tubing 48" to 53" long on cast material 72" on extruded
Specialize in: custom work and stock materials.
Personnel: see p. 1085

Conneaut Rubber & Plastics Co., Conneaut
Specialize in: custom compounding and extrusions
Pres.—J. M. W. Chamberlain
V. Pres.—R. C. Hunter
Sales Mgr.—J. H. Davison
Pur. Agt.—J. B. Phipps

Francis Industries, Pataskala (*2, A*)
Max. size molded tubing: 8 Ft. diameter 10 Ft. long
Specialize in: high strength, electrical and chemical tubing also tubular glass arrows
Pres. & Sls. Mgr.—R. J. Francis
V. Pres. & Pur. Agt.—C. A. Francis

●**General Tire and Rubber Co.,** Akron (*2, A*)
Personnel: see p. 1085

Glastic Corp. Cleveland (*2*)
Max. size laminated sheet: 36 x 72"
Specialize in: flat sheet laminates

Greene, Ray & Company, Toledo (*2*)
Pres.—Ray Greene
V. Pres.—Jan Greene
Sls. Mgr.—Robert Crist
Pur. Agt.—Ken Greene

●**Seiberling Rubber Co. Plastics Div.,** Newcomerstown (*1, 4, A*)
Max. size laminated sheet: 48" x 96"
Personnel: see p. 1086

PENNSYLVANIA

Allegheny Plastics, Inc., Coraopolis (*4*)
Max. size laminated sheet 30" x 30"
Max. size molded tubing
Standard length tubing: various

Calcon Mfg. Co., Inc., Washington
Specialize in: plastic extrusions, vinyl and poly vinyl chloride tubing 10" dia.
Pres. Joseph A. Morosco
Sls. Mgr.—James C. Morosco
Pur. Agt.—A. W. Moore, Jr.

Commonwealth Pipe & Tubing Inc., Philadelphia
Specialize in: extruded coating over solid or hollow cores.
Pres., Sls. Mgr. & Pur. Agt.—Harold B. Heft

Curry Arts Molding & Laminating Co., Scranton (*1, 2, A, B*)
Max size laminated sheet: 36" x 38"
Specialize in: acrylic decorative sheets (18" x 24")
Pres. & Partner, & Sls. Mgr.—Harry H. Rosenthal
V. Pres.—Kurt Adler
Partner and Pur. Agent-Kurt Adler

●**Laminations, Inc.,** Scranton (*4, A, B*)
Max. size laminated sheet: 54" x 144"
Pres.—John Mulpowney
Vice Pres.—M. J. Lynch

Plastic Laminating Co., Swarthmore (*1, 4, A*)
Max. size laminated sheet: 23¼ x 31"
Owner, Sales Mgr. & Pur. Agt.—Samuel M. Dodd, Jr.

●**Scranton Plastic Laminating Corp.,** Scranton (*2, 4, A, B*)
Max. Size laminated sheet: 50" x 108"
Personnel: see p. 1107

Strick Plastics, Perkasie (*2, 3, A*)
Max. size laminated sheet: 50" x 100"
Pres.—C. Bradford Sheppard
V. Pres.—Solomon Katz
Sales Mgr.—R. W. Jakubek

Synthane Corp., Oaks (*1, 2, A*)
Max. size laminated sheet: 36" x 36"; 72" x 36" 96" x 24"
Max. size rolled tubing: 26" OD
Max. size molded tubing 4" OD
Standard length tubing: 18"-36"-48"-96"
Specialize in: sheets, rods, tubes, molded macerated, molded laminated fabricated parts
Pres.—R. R. Titus
Sales Mgr.—E. E. Smith

●**United Laminators, Inc.,** Mayfield (*A, B*)
Max. size laminated sheet: 50" x 72"
Pres.—M. Bros
Vice Pres.—Herbert Perry

Washington Plastics Co., Sharon (*2, A, B*)
Pres.—Harry Northover.
V. Pres.—Paul Richley, Sr.
Sales Mgr.—Harry Northover

Westlake Plastics Co., Lenni Mills (*4, A*)
Max. Size Lam. Sheet: 20" x 40"
Personnel: see p. 1088

Willson Camera Co. Inc., Havertown (*1, A, B*)
Max. Size Lam. Sheet: 22" x 50"
Pres.—Thomas C. Willson, Jr.
V. Pres.—Nathan S. Weintraub
Sales Mgr.—Nathan S. Weintraub

RHODE ISLAND

Anchorage Plastics, Inc., Warren
Max. size rolled tubing: ½" to 30" Dia. x 10 ft. long
Standard length tubing: 10 ft.
Specialize in: Fibrous glass cloth polyester
Personnel: see p. 1088

SOUTH CAROLINA

Westinghouse Electric Corp., Micarta Division, Hampton (*1, 2, A, B*)
Max. size lam. sheet: 4' x 8'
Max. size rolled tub.: 96" length, 48" I. D.

● Indicates Advertiser.

Stand. length tub.: 48"
Gen. Mgr.—G. H. McBride
Sales Mgr.—S. F. Davies
Pur. Agt.—C. R. Keller

VIRGINIA

O'Sullivan Rubber Corp., Winchester (*4*)
Personnel: see p. 1107

Universal Moulded Products Corp., Bristol (*1, 2*)
Max. size rolled tubing: 32" Diameter
Standard length tubing 10 ft. and 20 ft.
Pres.—T. H. McKoy, Jr.
V. Pres.—Dr. Robert J. Nebesar
Pur. Agt.—J. G. Barnes

WASHINGTON

Pacific Plastics Co., Inc., Seattle (*1, 2, 4,*)
Pres. & Sales Mgr.—Ben Rosen
V. Pres.—Allen Rosen
Pur. Agr.—Bertha Seder

Western Plastic Inc., Spokane (*1*)
Max. Size: 6" x 6" (lam. sheet).
Pres. & Pur. Agt.—Gabe E. de Roetth
V. Pres.—Paul Houston
Sales Mgr.—Robert D. McGoldrick

WISCONSIN

● **Decar Plastic Corp.,** Middleton (*1, B*)
Max. size laminated sheet: 48" x 72" x 36" x 96"
Pres. & Sls. Mgr.—Ralph L. Fossier, Sr.
V. Pres. & Tech. Director:—T. Walter Noble
V. Pres. & Gen. Mgr.—George W. Johnson

Fiberesin Plastics Co., Oconomowoc (*1, B*)
Max. size laminated sheet 48" x 96"
Specialize in: school & office desk tops and furniture panels
Pres.—W. W. Turner
V. Pres.—David McCalla
Sales Mgr.—Robert W. Healy
Pur. Agt.—R. J. Lyman

Presco Plastics, Milwaukee (*1, 4*)
Max. size laminated sheet: Various size presses
Pres. & Pur. Agt. E. K. Schroeter
Manager—H. Schauf

Northern Plastics Corp., La Crosse (*1*)
Max. size lam. sheet: 39" x 47"
Personnel: see p. 1102

ENGLAND

BX Plastics Ltd., London (*4, A*)

● **Microcell, Ltd.,** London (*1, 2, 3*)
Max. size laminated sheet: 8' x 4'
Max. size rolled tubing: 8' long, x 12" dia.
Max. size molded tubing (Standard)
8' long x 2'6'
Standard length tubing: 8'
Pres.—Henry Kremer
V. Pres.—D. J. Hodgson & L. R. Rutherford
Sales Mgr.—E. Cook
Pur. Agt.—E. Hesk

REINFORCED PLASTICS PROCESSORS

CALIFORNIA

Airconductors, Compton
Types of molding done: low pressure plaster, plaster & metal molds. Tension wrap & vacuum bag molding
Type of resins and reinforcements used: thermal & thermal setting resins pre-impregnated in any cloth phenolics-epoxies—silicones—extreme Hi-temp resins for jet & missle use. Non-metallic sheeting, flexible & rigid. Custom molding military & aircraft. Also sewn products.
Pres.—Fred E. Sindars
V. Pres.—D. C. Cairns
Sales Mgr.—F. Sindars
Pur. Agt.—H. Sindars

Automatic Plastic Molding Co., Berkeley
Presses: 4–12 x 12 platen 24" daylight; 2–16" x 18" platen 28" daylight; 2–28" x 32" platen 32" daylight; 1–14" x 14" platen 26" daylight; compression with matched steel molds 9 fiberglass presses.
Type of resins and reinforcements used: polyester resin
Number preformers: 2–28" 2 Preform ovens.
Pres.—Forrest Engelhart
V. Pres. & Sales Mgr.—A. J. Carlson
Pur. Agt.—Forrest Barnes

Chemold Company, Santa Monica
Types of molding: Hydraulic press molding on matched metal dies.
Presses: 4–75 ton 3' x 5', 48" daylight; 2–150 ton, 4' x 8', 72" daylight; 1–750 ton, 92" x 130", 40" daylight.
Size of flat laminate sheet: 4' x 12' maximum
Type of resins and reinforcements used: polyesters, epoxies, phenlies, glass mat, glass cloth, chopped roving.
Number and sizes of preformers: 1–48" with ancillary over equipment.
Type of fabrication: any custom molding of contoured parts; flat and ribbed building panels and laminated plywood foam, and honey comb up to 4' x 12'
Pres.—K. D. Smith
V. Pres.—L. R. Dailey
Sales Mgr.—E. Eberli
Pur. Agt.—Peter Hunt

Chemtron Fiber Glass Co., El Monte
Types of molding done: contact, vacuum, press, cold molding; steel aluminum—wood, reinforced plastics, plaster.
Presses: 1–24" x 24" x 30"; 1–60" x 120" x 36"; 1–48" x 48" x 72"; 1–30" x 60" x 60"; 1–30" x 54" x 48"
Size of flat laminate sheet made: 60" x 120"
Type of resins and reinforcements used: Epoxy-polyester, phenolic, glass cloth, mat-roving, Sisal Jute, etc.
Type of fabrication: vacuum, molded, hand lay up, matched die cold forming.
Personnel: see p. 1074

Copolymer Corp., Los Angeles
Types of molding done: compression steel aluminum.
Presses: 9 presses 60" x 120" x 250 ton
Type of resins and reinforcements used: polyester, epoxy-phenolic, fibrous-glass
Number and sizes of preformers: One 45" Preform
Type of fabrication: assembling
Pres.—John. H Wyckoff

Crest Molded Products, Inc., Arcadia
Number and sizes of preformers: One–2½" single-stroke.
Pres.—Charles Martins
V. Pres.—Stephen Civerolo
Sales Mgr. & Pur. Agt.—K. R. Mergen

Eldon Mfg. Co., Los Angeles
Types of molding done: match metal, bag molding, contact lay up.
Type of resins and reinforcements used: phenolic, epoxy, polyester, silicone
Number of sizes of preformers: Number: 1
Type of fabrication: high pressure, high temperature ducts, honey comb structure, dry ply and wet lay-up.
Pres.—Robert Silverstein
V. Pres.—Walter Burroughs
Sales Mgr.—Darrel Francy, Gen. Mgr.
Pur. Agt.—Louis Berkowitz

Filon Plastics Corp., El Segundo
Type of molding done: fibrous-glass and nylon reinforced polyester, resin building panel under the trade name Filon These panels are produced on a patented, continuous electronically controlled process.
Size of flat laminate sheet: Widths of 24", 30", 36" and 48", standard lengths of 8', 10', and 12' available also in roll lengths. Maximum width 48" and standard thicknesses 1/32", 3/64", 1/16" and 3/32"
Type of resins and reinforcements used: light stabilized polyester resin and silane finished glass fibers.
Pres.—D. S. Perry
V. Pres.—Manufacturing: G. R. Huisman
Sales Mgr.—Alex Zakarian
Pur. Agt.—Frederick A. Nichols

● Indicates Advertiser.

General Fiber, Inc., Div. of General Plastics Corp., Los Angeles
Types of molding done: fibrous glass and polyester resin; premix. Matched hardened steel dies.
Presses: 4–16 x 18 DL 27, 2–18 x 28 DL 28, 1–32 x 40 DL 32, 1–24 x 30 DL 18, 1–48 x 48 DL 54, 1–30 x 40 DL 48
Type of resins and reinforcements used: polyester, fibrous glass, sisal, and inert fillers.
Personnel: see p. 1108

Gill, M. C., Corp., El Monte
Types of molding done: flat sheet, formed parts.
Presses: 1–72" x 168", 48" daylight; 1–20" x 38", 24" daylight.
Size of flat laminate sheet: Max. 72" x 168", Std. 48" x 144"
Type of resins and reinforcements used: polyester, epoxy, phenolic, silicone, all low pressure—fillers, glass, cotton, paper & jute
Pres. & Sls. Mgr.—M. C. Gill
V. Pres. & Pur. Agt.—E. W. Gill

Lynch Asbestos Co., Los Angeles
Continuous laminating: glass, 42" wide
Type of resins and reinforcements used: polyester-glass
Pres.—R. O. Lynch
V. Pres.—J. C. Hunter
Pur. Agt.—C. Gruen

Marplex Co., El Segundo
Types of molding done: matched metal molds
Presses: 9 presses: 24" x 24" platens to 30" x 40" platens daylight 3' to 5'
Size of flat laminate sheet: 2' x 3'
Type of resins and reinforcements used: polyester resins, fibrous glass reinforcement
Number and sizes of preformers: 3, to 30" dia.
Type of fabrication: specializing in lamp shades & misc. lighting parts, giftware, misc. custom molding.
Pres. & Gen. Mgr.—E. Marx
Pur. Agt. & Factory Mgr.—H. Mayer

Mica Corporation, Culver City
Types of molding done: printed circuit, epoxy glass cloth, copperclad & unclad laminate.
Presses: 1 press, 8 platens, 4" daylight
Size of flat laminate sheet: 18" x 36"
Type of resins and reinforcements used: epoxy glass cloth.
Personnel: see p. 1090

Olympic Plastics Co., Inc., Los Angeles
Types of molding done: matched metal molding.
Presses: 11, 36 tons, 150 tons platens to 4' x 5', daylight to 7'.
Number and sizes of preformers: 1–36".
Pres.—David Rome
V. Pres.—David C. Siteman
Chief Engr.—Willard Lundberg
Pur. Agt., Secy.-Treas.—Harry Scott

Omohundro, Paul, Company, Paramount
Types of molding done: membrane molding, press molding
Presses: 1–0–96" daylight; 87" x 48" platen, 1–0–84" daylight; 51" x 36" platen.

Type of resins and reinforcements used: polyester, epoxy, phenolic, silicone with fibrous glass.
Type of fabrication: military specification parts for aircraft, missiles & electronics.
Pres.—Paul Omohundro
V. Pres.—James R. Johnson
Pur. Agt.—G. Sigurdson

Parker Manufacturing Co., San Diego
Types of molding done: low pressure flat & corrugated sheet.
Size of flat laminate sheet: flat 42" x 144", maximum corrug. 40" x continuous
Continuous laminating: widths: 26", 27½", 34" & 40"
Thickness: .050 (1¼ oz.), .060 (2 oz.), .090 (3 oz.), glass
Type of resins and reinforcements used: unsaturated polyester, reinforcement, fibrous glass
Type of fabrication: translucent reinforced fiberglass building sheets, corrugated & flat, & butler corrugation.
Personnel: see p. 1090

Plastic Age Sales, Inc., San Fernando
Types of molding done: all types metal molds, reinforced molds, mat molds, fabric layup, gunk molding.
Presses: see compression presses.
Size of flat laminate sheet: 48" x 120".
Type of resins and reinforcements used: glass, nylon, orlon, mineral, asbestos, polyester, alkyd, silicone, D. A. P., phenolics
Number and sizes of preformers: 1–custom-size unlimited.
Personnel: see p. 1090

Polyply Company, San Diego
Size of flat laminate sheet: 48" x 96"
Type of resins and reinforcements used: polyester.
Pres.—George A. Baker

Reflin Co., San Diego
Types of molding done: centrifugally molded fibrous glass reinforced plastic pipe
Type of resins and reinforcements used; polyester, fibrous glass, mat and cloth
Pres. & Sales Mgr.—Louis L. Potomac
Pur. Agt.—L. P. Kehres

Reinforced Plastic Tubing Co., Gardena
Types of molding done: laminating fiber glass tubing
Proprietor—Bernard Robinson

Reinhold Engineering & Plastics Co., Norwalk
Types of molding done: laminating, vacuum type molds and matched metal, high pressure-steel mated tooling; glass filament winding-mandrels.
Presses: high pressure reinforced glass moldings use standard compression presses listed under custom molders.
Size of flat laminate sheet: glass laminated sheet, phenolic resin to 4 ft. square.
Continuous laminating: glass tubing 3 to 3½" ft. widths, various thicknesses
Type of resins and reinforcements used: glass cloth, epoxy resins, phenolic resins and polyester resins.
Type of fabrication: aircraft component assemblies and rocket and missile details; filament winding of rocket motor tubes
Personnel: see p. 1090

Rippolite Plastic Products, Inc., Burbank
Size of flat laminate sheet: 40" x 8' x 10".
Type of resins and reinforcements used: polyester resins and fibrous glass reinforcements.
Personnel: see p. 1090

● **Swedlow Plastics Co.,** Los Angeles
Presses: 11 presses; max. area 5' x 10'; max. daylight 80".
Size of flat laminate sheet: max. 5' x 10'.
Continuous laminating: .005 to .100–36" to 60" width.
Type of resins and reinforcements used: fibrous glass, nylons, cotton, paper polyester, acrylics, nylon.
Number and sizes of preformers: 1–48"
Personnel: see p. 1090

Thompson, H. I., Fiber Glass Co., Los Angeles
Types of molding done: aircraft reinforced glass plastic, matched metal & vacuum-bagged molds.
Presses: (2) 3' x 4' x 9' daylight; (2) 3' x 3' x 2' daylight; (2) 2' x 2' x 6' daylight; (1) 2' x 2' x 18" daylight; (1) 1' x 1' x 2' daylight.
Size of flat laminate sheet: 3' x 4' maximum.
Type of resins and reinforcements used: polyesters, epoxies, phenolics, and silicones, on glass and asbestos.
Number and sizes of preformers: One (1) 3' x 3'.
Type of fabrication: aircraft radomes, preform, and compression molding.
Pres.—Harry I. Thompson
V. Pres., Executive—William C. Winterhalter
Sales Mgr.—William E. Benke
Pur. Agt.—Edward C. Titus

Wal-Mar Plastics, Inc., Torrance
Types of molding done: cast form blocks, laminated hydro-press dies, drop hammer dies, holding fixtures, matched laminated dies, plastic patterns.
Type of resins and reinforcements used: epoxy, polyester, glass cloth and mat.
Type of fabrication: dies, holding fixtures, patterns and master patterns.
Pres.—Wallace J. De George
V. Pres.—Mark L. De George
Sales Mgr.—Ritson A. Ballinger
Pur. Agt.—John W. Burgess

Wizard Boats, Inc., Costa Mesa
Types of molding and molds used: contract and vacuum laminating, low pressure, male or female-oven curing.
Resin and reinforcements used: polyester resin, glass cloth, woven roving, glass mat for reinforcement.
Fabrication: boats, swimming pools, astrodomes, bathtubs, boxes.
Pres.—Harold Hauflaire.
V. Pres.—C. D. Horne, C. B. Melone
Sales Mgr.—C. D. Horne
Pur. Agt.—R. A. Hawley

COLORADO

Plasticrafts, Inc., Denver
Types of molding done: matched metal molds
Presses: 4 Presses
Type of resins and reinforcements used: polyester, glass cloth and mat, epoxy
Pres.—T. H. Cooper
V. Pres. & Sales Mgr.—B. B. Butcher
Pur. Agt.—T. H. Cooper

CONNECTICUT

Bridgeport Moulded Products, Inc., Fairfield
Number and size of pref.: 5, misc.
Personnel: see p. 1106

● Indicates Advertiser.

Plastic Film Corp., Plainfield
Continuous Laminating: 60" width range on paper, glass and cloth
Type of resins and reinforcements used: vinyl & polyethylene
Personnel: see p. 1076

●**Waterbury Companies, Inc.,** Waterbury
Types of molding and molds used: taw pressure
Presses, platen area and daylight space: 1-113 Ton, 1-27 ton, 1-semi auto., 3 Stu Preform
Personnel: see P. 1075

DELAWARE

●**Continental-Diamond Fibre Corp.,** Newark
Types of Molding: phenolic and polyester
Size of flat laminate sheet made: 38" x 72" polyester laminate
Type of resins and reinforcements used: paper, cotton fabrics for phenolics glass mat for polyesters.
Type of fabrication: drilling, sawing, turning
Personnel: see p. 1076

Haveg Industries, Inc., Wilmington
Types of molding done: 6
Presses: 6 up to 5' x 7'
Type of resins and reinforcements used: all types & thermoplastics, and thermosetting polymers.
Number and sizes of preformers: 2

●**National Vulcanized Fibre Co.,** Wilmington
Types of molding done: low pressure laminated sheet using matched metal molds
Presses: 1-36 x 96, 5" daylight; 1-36 x 46, 3¼" daylight; 1-36 x 42, 1¾" dayligh
Type of resins and reinforcements used: polyester resin with glass mat and roving
Number and sizes of preformers: 1" to 40' dia.
Type of fabrication: complete fabrication service
Personnel: see p. 1076

FLORIDA

Glascraft Co., Jacksonville
Types of molding done: Fibrous glass boats, tanks, custom-molding, metal, plastic molds
Type of resins and reinforcements used: all types of glass polyester-epoxy
Owner—Milton Dobrin

Lami-Plast Products Co., Tampa
Types of molding done: custom, acid tanks, ducts, & hoods boats steel, plastic and wood molds.
Type of resins and reinforcements used: polyester epoxy
Type of fabrication: custom molding
Pres., Sls. Mgr. & Pur. Agt.—Bernard N. Rothenberg
V. Pres.—Mary P. Rothenberg

Southern Plastic Products Co., Riviera Beach
Types of molding done: hand lay-up
Type of resins and reinforcements used: epoxy, polyester & fibrous glass
Type of fabrication: tooling and tool jigs
Pres. & Sales Mgr.—Tom Nuttall, Jr.
V. Pres. & Secy.—Veronica A. Nuttall

ILLINOIS

Bacon & Weber, Chicago
Type of fabrication: fibrous-glass, reinforced-castings in epoxy's or phenolics.

●**Brunswick-Balke-Collender Co.,** Chicago
Types of molding done: vacuum-bag molding, press molding, contact plaster, epoxy, metal spray, alum, steel.
Number of presses: 6 presses, platens; 4' 3" x 2' 2" to 6' x 8', daylight; opening up to 12'.
Type of resins and reinforcements used: polyester, phenolic, epoxy, fibrousglass cloth, mat.
Fabrications: radomes, honeycomb, for, sanwich, solid laminate.

Chicago Price Tag Mfg. Co., Chicago
Size of flat laminate sheet: 18" x 18"
Type of fabrication: (plastic-rigid & flexible sheet) embossing and die cutting.

●**Commercial Plastics Co.,** Chicago
Types of molding done: houseware item and custom molding for automatic & refrigeration mfg.
Pres.—Anton Scharl
Vice Pres.—Raymond Akter
Sls. Mgr.—E. W. Heeter

Crane Packing Co., Morton Grove
Types of molding: compression.
Type of resins and reinforcements used: teflon reinforced with glass fiber, carbon, graphite, copper, bronze, talc, calcium, fluoridex of other organic materials.
Pres.—Karl V. Rohlen
V. Pres.—Carl E. Schmitz
Sls. Mgr.—Vance E. Vorhees
Pur. Agt.—V. Grogleth

●**General American Transportation Corp., Plastics Div.,** Chicago
Types of molding done: matched metal molding.
Presses: 9 presses from 100 ton to 1000 ton.
Type of resins and reinforcements used: various types of resins with all types of fiber reinforcements.
Number and sizes of preformers: 5 Preform machines.
Pres.—William J. Stebler
V. Pres.—Frank E. Selz
Gen. Mgr.—Harry M. Jenkins
Pur. Agt.—Robert B. Silverman (Plastic Division)
Supervisor of Sales—James Nash
Director of Research & Development—Carl F. Massopust

●**Hawley Products,** St. Charles
Types of molding done: fiberous glass, pre form matched metal molds.
Number of presses: 1-60" x 84"-60" day; 1-30 x 40"-60" day; 3-30 x 40"-48 day.

Keystone Plastic Engineering Co., Chicago
Types of molding done: boats, polyestgr epoxy.
Type of resins and reinforcements used: polyester, epoxy, glass mat, glass cloth.
Type of fabrication: boats, misc.
Pres.—Fred M. Schukraft
Vice Pres.—Bernard Schukraft
Sales Mgr. & Pur. Agt.—Richard Schukraft

Multiplastics, Div. of Curd Enterprizes, Addison, Ill.
Types of molding done: vacuum, hand lay up & compression.
Size of flat laminate sheet: 4' x 10'.
Type of resins and reinforcements used: polyester, epoxy.
Personnel: see p. 1077

●**Molded Products, Division of Admiral Corp.,** West Chicago
Types of molding done: custom compression with matched metal molds; custom compression with epoxy plastic molds, hand lay up molding.
Type of resins and reinforcements used: all types of resins and glass sisal reinforcements.
Number and sizes of preformers: 2 with 36" turntables; 1 with 72" turntables; 1 with 48" turntables.
Personnel: see p. 1077

●**Plasticrafters, Inc.,** Chicago
Types of molding done: compression, steel molds.
Presses: 6 presses: 24" x 36" x 24" daylight.
Size of flat laminate sheet: 36 x 144.
Type of resins and reinforcements used: fibrous glass reinforced thermosetting resins.
Personnel: see p. 1077

●**Richardson Company,** Melrose Park
Type of fabrication: all types of machining.

Plano Molding Company, Plano
Number and sizes of preformers: 3-10 to 25 ton.
Pres.—James L. Henning
V. Pres. & Sales Mgr.—R. C. Yunger

United Die Models Inc., Chicago
Type of molding done and molds used: contact, vacuum bag, compression molding, plastic and wooden molds.
Resins and reinforcements: polyester and epoxy resin, glass cloth, mat and milled fiber.
Fabrication: duplication models, prototypes.
Pres.—Edwin R. Knize
V. Pres.—Elmer J. Knize
Sales Mgr. & Pur. Agt.—Alois R. Heinol

INDIANA

●**Amos Packaging,** Edinburg
Continuous Laminating: up to 48" width, up to .010" thick-paper, foils, films, extrusion coated and laminated with polyethylene
Pres.—Dale Amos
Vice Pres.—J. C. Kazimier
Sales Mgr.—Hamilton Moran
Pur. Agt.—Walter Parmer

●**General Tire & Rubber Co.,** Marion
Types of molding done: vacuum bag, contact, match, metal molding
Presses: 35 presses: platen areas ranging from 32" x 34" to 72" x 84", daylight to 96", tonnage 50 ton to 700 ton.
Size of flat laminate sheet: 4' x 01 sheet, thickness to ½".
Type of resins and reinforcements used: polyester epoxy, silicones, glass mat, roving, cloth, also sisal.
Number and sizes of preformers: 4 up to 48" dia.
Type of fabrication; mold, drill, sand.
Pres.—W. O'Neil
V. Pres.—H. M. Dodge
Sales Mgr.—Fred W. Dover

●**Polygon Plastic Company,** Walkerton
Type of resins and reinforcements used: polyester and epoxy; fibrous glass reinforcements.

●Indicates Advertiser.

Pres.—S. M. Shobert
V. Pres.—G. S. Parks
Sales Mgr.—E. R. Jaques

Plas-Steel Products, Inc., Walkerton
Types of molding done: extrusion of reinforced fiber glass rod stock.
Pres.—S. M. Shobert
V. Pres.—G. S. Parks
Sales Mgr.—E. M. Elliott

Pribble Plastics Products, Inc., New Haven
Types of molding done: hand lay-up, vacuum bag, matched metal.
Presses: 2-18 x 20, 28" Daylight, 2-13 x 18, 28" daylight; 1-30 x 36", 40" daylight.
Type of resins and reinforcements used: polyester, glass mat and cloth.
Pres., Sales Mgr. & Pur. Agt.—Wayne I. Pribble
V. Pres. & Plant Mgr.—John L. Haugarud

IOWA

Thombert, Inc., Newton
Type of fabrication: punching, sawing, drilling, turning, shearing.
Pres., Sales Mgr. & Pur. Agt.—Robert L. Smith
V. Pres.—Wilbur E. Edwards

KANSAS

Engineered Plastics, Inc., Baxter Springs.
Type of resins and reinforcements used: polyester, epoxy, epoxy-polyamid resins, glass fibres, dacron, etc.
Type of Fabrication: filament winding of spheroids, 6" min. through 59" dia.; reinforced tubes, 1½" I. D. thru 14" I. D. any wall x 20 ft. long, round or rectangular, straight or tapered.
Gen. Mgr.—W. Blake
V. Pres. & Prod. Engr.—C. K. Norris
Field Engr.—J. V. Smith
Sales Mgr.—R. J. Harris

Lamicell Engineering Co., Baxter Springs
Types of molding done: matched metal, bag, & hand lay-up.
Presses: 1-150 ton, 40" x 44" platen, 30" stroke, 60" daylight; 3-24" platen x 24" stroke, 35" daylight.
Type of resins and reinforcements used: polyester, epoxy, epoxy-polyamid.
Pres. & Gen. Mgr.—W. R. Blake
V. Pres. & Sales Mgr.—C. B. Nelson
Sales Mgr.—W. A. Barnett

Plastic Fabricating Co., Inc., Wichita
Types of molding done: low pressure laminating, glass-preform molding & premix from plastic, plaster and matched metal molds.
Presses: 36 x 48 platen, 48" daylight; 20 x 30 platen, 18" daylight; 40 x 50 platen, 60" daylight, 38 x 48 platen, 48" daylight, 30 x 30 platen, 36" daylight, (5 presses).
Type of resins and reinforcements used: resins: polyester, modified polyester, epoxy, phenolic: reinforcements, fiberglass, woven cloth, fibrous-glass mat, fibrousglass-preform, asbestos, sisal.
Number and sizes of preformers: 48" preform machine.

Type of fabrication: aircraft ducting, aircraft structural & non-structural, reinforced plastic parts, photographic accessories (trays, sinks, etc.).
Pres. & Sales Mgr.—Felix M. Farrell
V. Pres.—Joe H. Yeager
Pur. Agt.—John W. Hickman

KENTUCKY

Production Aid, Inc., Middletown
Type of resins and reinforcements used: epoxy, glass, asbestos, silica, metallic powders.
Type of fabrication: wet lay-up casting machining.
Pres.—T. E. Vassar
V. Pres.—J. S. Sutherland

MARYLAND

Artmor Plastics Corp., Cumberland
Types of Molding done: architectural panels & components via matched metal dies.
Presses: 3-Approx. 36 x 48, 20" daylight
Type of resins and reinforcements used: polyester, acrylic, with fibrousglass, orlon, other synthetics
Personnel: see p. 1103

Chance, W. R., & Associates, Inc., Waldorf
Types of molding: vacuum molding & open molding.
Type of resins and reinforcements used: polyester & epoxy resins, glass reinforcement.
Type of fabrication: development prototypes and production of large structures.
Pres.—W. R. Chance
Treas.—J. R. Riggleman, Jr.
Sales Mgr.—D. P. Hains
Secy.—Miss R. Wittschiebe

MASSACHUSETTS

Beetle, Carl N., Plastics Corp., Fall River
Types of molding done: hand lay-up, bag molding, matched metal plaster, wood, plastic, metal.
Type of resins and reinforcements used: polyester, epoxy glass, nylon, sisal etc.
Type of fabrication: tanks, stacks, ducting, radomes, vents, hoods and housings.

Church, C. F., Division of American Standard, Holyoke.
Types of molding done: matched metal molds in hydraulic presses.
Presses: 1-100 ton, 48 x 48 x 48" stroke, 1-80 ton, 24 x 24 x 16" stroke.
Type of resins and reinforcements used: polyesters, epoxy, fibre glass, sisal.
Number and sizes of preformers: 1-double 36"
Type of fabrication: hand lay-up.
Pres.—R. A. Witherell
V. Pres.—S. L. Young
Sales Mgr.—R. Kolstad
Pur. Agt.—L. Shaw

Emerson & Cuming, Inc., Canton
Types of molding done: matched mold, vacuum bag.
Presses: 4
Size of flat laminate sheet: on special order only.
Type of resins and reinforcements used: polyester, epoxy, fibrous-glass cloth, mat.
Type of fabrication: for electronics industry.
Pres.—C. L. Emerson, Jr.
V. Pres.—W. R. Cuming
Sales Mgr.—E. W. Anderson
Pur. Agt.—John F. O'Brien

Jupiter Plastics, Inc., Pittsfield
Types of molding done: lay-up
Pres.—Daniel C. Hurlbut
V. Pres. & Sls. Mgr.—Joseph Hines
Pur. Agt. & Treas.—Norman J Shalett

Laminated Sheet Products Corp., Norwood
Type of fabrication: machining, engraving, forming, marking.
Personnel: see p. 1091

McMillan Industrial Corp., Ipswich
Types of molding done: low pressure laminate radomes & custom shapes, cast aluminum molds.
Size of flat laminate sheet: 4' x 8'
Type of resins and reinforcements used: polyester, epoxy, phenolic, glass mat, fibrousglass cloth.
Type of fabrication: radomes, tubes, rods, sheets custom shapes, insulated panels (foam sandwich).
Pres.—Edward B. McMillan
Sales Mgr.—Arthur M. Brink
Pur. Agt.—A. Clark

●**Sandman, Eli, Co.,** Worcester
Continuous Laminating: on fibrous-glass, cotton, cloth, paper and all synthetic fabrics.
Type of resins and reinforcements used: phenolics, epoxies, polyesters and vinyls.
Type of fabrication: impregnating and coating.
Personnel: see p. 1106

Trimount Plastic Co. Inc., Arlington
Presses: 4 presses-1-10 x 10 x 12"; 2-24 x 54 x 30"; 1-54 x 112 x 36".
Size of flat laminate sheet: 24 x 38, 54 x 112, 24 x 54.
Type of resins and reinforcements used: epoxy, glass, cloth, laminates, copper clad & unclad.
Personnel: see p. 1091

MICHIGAN

Ameriplastic Company, Flint
Types of molding done: hand lay-up, wood, plaster, metal and plastic molds.
Type of resins and reinforcements used: polyester, epoxy, glass, sisal.
Type of fabrication: custom
Personnel: see p. 1079

Duralastic Products Co., Detroit
Types of molding done: mat laminates, premix molding.
Presses: 20- maximum size, 36" x 72" x 30" strokes up to 150 tons; platen up to 48" x 72", daylight 48", strokes 36".
Size of flat laminate sheet: 3' x 6.
Type of resins and reinforcements used: polyester, phenolic, epoxy glass, sisal.
Type of fabrication: riveting, stapling.
Pres.—Joseph N. Epel
V. Pres.—Julius Barach
Sales Mgr.—Joseph N. Epel
Pur. Agt.—James R. Pollock

●**Fabricon Products, Div. of Eagle-Picher Co.,** River Rouge
Types of molding done: compression molding-reinforced plastics.

●Indicates Advertiser.

Presses: Up to 42 x 60, max. daylight 65".
Type of resins and reinforcements used: polyester resins, fibrous-glass and sisal reinforcements.
Number and sizes of preformers: 1–48" x 48".
Personnel: see p. 1080

Harstil Industries Co., St. Clair Shore
Types of molding done: specialize in laminated rolled tubing and contact molding of large custom parts.
Type of resins and reinforcements used: epoxy and polyester, resins, glass cloth or mat as required.
Type of fabrication: laminated tubing, contact molding of stock 24' cruisers, low production using matched plastic molds.
Personnel: see p. 1092

Haskelite Mfg. Corp., Grand Rapids.
Size of flat laminate sheet: 48 x 144
Continuous laminating: .018 & .032 glass.
Type of resins and reinforcements used: polyester resin.
Personnel: see p. 1092

Michigan Fiberglas Sales, E. Detroit
Types of molding done: hand lay-up, plaster & fibrous-glass.
Type of resins and reinforcements used: polyester & epoxy.
Type of fabrication: prototype & products.
Pres. & Sales Mgr.—E. D. Ireson, Jr.
V. Pres. & Pur. Agt.—Julian F. Ireson

Morrell, George, Corporation, Muskegon Heights
Types of molding done: compression and transfer molding.
Type of resins and reinforcements used: polyester, epoxies, fibrous-glass, asbestos, sisal.
Pres.—John Reardan
V. Pres. & Pur. Agt.—Albert Lyonnais
Sales Mgr.—C. Joseph Kaskie

Plastic Masters, Inc., New Buffalo
Number and sizes of preformers: 1–80 tons, 1–60 tons, 1–35 tons.
Pres.—Victor A. Miller
V. Pres.—Owen E. Skelton
Gen. Mgr.—Carl G. Marquardt
Sales Mgr.—Richard P. Smith
Pur. Agt.—Bernard A. Guerrettaz

Reynolds Plastics, Inc., Walled Lake
Types of molding done: steel, aluminum, epoxy.
Presses: 2–26" x 24" x 18" opening, 12" x 18" x 11" opening.
Type of resins and reinforcements used: polyester and epoxy.
Type of fabrication: custom and production.
Personnel: see p. 1092

MINNESOTA

●**Northwest Plastics, Inc.,** St. Paul
Types of molding done: compression, steel, hand lay-up, epoxy.
Presses: same as compression.
Type of resins and reinforcements used: epoxy, polyester, glass.
Type of fabrication: largely hand lay-up.
Pres.—J. R. Frevermuth
V. Pres. & Chief Engr.—W. H. Mahle
Sales Mgr.—F. T. Thiets
Pur. Agt.—R. J. Twiss

Sperzel Co., Minneapolis
Presses: 4–42" x 36"
Pres. & Pur. Agt.—M. J. McCabe
V. Pres.—A. Deinard
Sales Mgr.—H. H. Reinhard

MISSOURI

Hanley Plastics Company, St. Louis
Types of molding done: hand lay-ups, matched metal die, etc. Steel, plaster, epoxy, etc.
Presses: 1 compression press, 18" x 22" bed, 22 ton, daylight 15"; misc. presses.
Size of flat laminate sheet: Laboratory: 10" x 8"
Type of resins and reinforcements used: fibrous-glass reinforced polyester, fibrous-glass reinforced epoxy, and isocynate foams.
Type of fabrication: product development and pilot runs by compression moulding, hand lay-ups etc.

Kelley, George A., Fredericktown
Type of fabrication: centerless grinding screw machine parts formed extrusions punching etc.
Personnel: see p. 1092

Kopplin Molding Corp., St. Louis
Types of molding done: polyester, glass
Presses: 8–75 to 200 ton, 20–36" daylight

Regal Plastic Co., Kansas City
Type of molding done: bag molding, hand lay-up, gunk, matched metal dies.
Presses: 3 Hydraulic presses: 48 x 42, 72" daylight; 30" x 30", 72" daylight; 18" x 16", 24" daylight.
Type of resins and reinforcements used: polyester, fibrous-glass, epoxy, sisal.
Number and sizes of preformers: 1–48" preformer.
Type of fabrication: all kinds.
Pres., Chairman of Board of Directors & Sales Mgr.—J. S. Kivett
V. Pres. & Chief Engr.—N. D. Gallagher
Asst. Sales Mgr.—W. L. Short
Pur. Agt.—Paul E. Snow

NEBRASKA

Kerr, R. W., Plastic Co., Hastings
Types of molding done: matched metal molds.
Presses: 3-up to 35" x 46" platen size with 16" stroke.
Size of flat laminate sheet: 18" x 24" thermoplastic
Type of resins and reinforcements used: most all types.
Type of fabrication: most all types.
Personnel: see p. 1092

Kerrco Products, Lincoln
Types of molding done: Matched steel molds
Presses: 3-up to 35" x 46", 26" daylight opening.
Type of resins and reinforcements used: polyesters and epoxies, glass and sisal.
Type of fabrication: all types.
Personnel: see p. 1092

Omaha Plastics Co., Omaha
Types of molding done: expoy casting, aluminum molds.
Type of resins and reinforcements used: epoxy, fibrous-glass, cloths, mats and dacron.
Pres. & Pur. Agt.—George D. Kahn
V. Pres.—Jewel K. Kahn

NEW HAMPSHIRE

Keller Products, Inc., Manchester
Types of molding done: fabricator.
Continuous Laminating: 4' x 10'.
Types of resins and reinforcements used: polyesters.
Type of fabrication: laminating large building panels.
Personnel: see p. 1092

NEW JERSEY

American Molded Fiberglass Co., Paterson
Types of molding done: hand open lay-up of large parts on fibrous-glass reinforced plastic molds; vacuum & match metal molding.
Presses: 3 presses (2–6' x 1'–2' daylight); (1 2' x 2'–2' daylight)
Type of resins and reinforcements used: polyester, epoxy with fibrous-glass, cotton, asbestos and sisal fibre.
Type of fabrication: all types of fabrication, specialize in large parts.
Pres.—S. Quentzel
Secy. & V. Pres.—H. Quentzel

Carpenter, L. E., & Co., Wharton
Continuous laminating: 56" finished width thickness-various.
Type of resins and reinforcements used: polyvinyl chloride.
Type of fabrication: conversion.
Pres.—George Lucas, Jr.
V. Pres.—J. V. Medici
Sales Mgr.—John Foster
Pur. Agt.—Arthur W. Mitchell

Electronic Mechanics, Inc., Clifton
Types of molding done: compression on glass bonded mica steel; both laminate and custom molding.
Size of flat laminate sheet: 14" x 19", 19 x 29.
Type of fabrication: complete machine shop for all types fabrication on glass bonded mica.
Pres.—D. E. Replogle
Treas. & Pur. Agt.—N. E. Brown
Sales Mgr.—J. E. Nester

Gemar Mfg. Co., Inc., Linden
Continuous laminating: 54" with 0005 to 030 paper, cloth plastics.

Hunter Plastics Co., Englewood
Type of fabrication: thermo plastic only.
Pres. & Sales Mgr.—Charles H. Hunter
V. Pres.—Frank J. Van Segvelt
Pur. Agt.—Frank J. Van Segvelt

Jersey Plastic & Die Casting Co., Irvington
Types of molding done: fibrous-glass reinforced polyester
Pres.—Patrick B. Zazzara
Gen. Mgr.—Nicholas L. Zazzara
Sales Mgr.—Berkeley A. Cater
Pur. Agt.—Jos. Circhirillo

Plastic Laminating Corp., Vaux Hall
Presses: 2–24 x 26, 1–24 x 54, 1–38 x 48.
Size of flat laminate sheet: 24 x 26, 24 x 31, 24 x 42, 24 x 48, 24 x 54, 38 x 48.
Personnel: see p. 1092

●**Polyplastex United, Inc.,** Union
Presses: 1 press; platen area–48" x 96"; daylight space 3".
Size of flat laminate sheet: 48" x 96".
Continuous laminating: width 60", thickness .025" use paper, glass & cloth.
Personnel: see p. 1106

● Indicates Advertiser.

Spiral Glas Pipe Co., New Brunswick
Continuous laminating: continuous pipe laminating.
Types of resins and reinforcements used: fibrous-glass reinforced DAP polyesters.
Type of fabrication: tubular goods.
Personnel: see p. 1092

Springfield Fabrications, Inc., Springfield
Type of fabrication: thermoplastic components made to customers' specifications.
Pres.—Henry F. Colvin
V. Pres.—Esther F. Colvin
Secy.—Treas.—Samuel H. Friedman
Pur. Agt.—J. F. Sweeney

Winner Mfg. Co., Inc., Trenton
Molding: Matched die, pressure bag, vacuum; molding on steel, alum, plastic dies.
Type of resins and reinforcements: glass, vegetable, synthetic with polyester and epoxy.
Number and size of preformer: 1-48"
Fabrication: all
Pres.—I. M. Scott
V. Pres.—H. L. Darby and J. Rosenwald II
Pur. Agt.—D. A. White

NEW YORK

DuBois Plastic Products, Inc., Buffalo
Types of molding done: custom molding, premix materials, matched metal molds.
Presses: 1-48" x 84" x 53" daylight, 1-44" x 46" x 39" daylight, 1-40" x 40" x 40" daylight, 1-36" x 43" x 38¼" daylight, 1-24" x 24" x 36" daylight, 1-20" x 20" x 30" daylight. Total 6 presses.
Pres.—N. J. Taylor
V. Pres. & Gen. Mgr.—R. A. Bright
Sales Mgr.—J. H. Ehrhardt
V. Pres.—W. F. Sterne
Pur. Agt. & Asst. Gen. Mgr.—R. V. Shear

Durable Formed Products, Inc., New York
Types of molding done: pre-impregnated fibrous-glas, low pressure molding.
Presses: 3 presses, size of platen 36" x 36", stroke 18"
Pres.—Vito A. Tanzi
V. Pres.—Robert A. Gerardi
Sales Mgr.—Allan M. Selig
Pur. Agt.—Thomas McManus

Emerson Plastics Corp., Bronx
Type of fabrication: precision fabricator of all plastic materials.
Pres.—W. Elsfelder
V. Pres.—I. Elsfelder
Sales Mgr.—A. Margosian
Pur. Agt.—D. Singer

Fairchild Guided Missiles Div., Fairchild Engine & Airplane Corp., Wyandanch
Types of molding done: vacuum bag, autoclave, matched die, mandrel winding and premix.
Presses: (7) presses-maximum size 84" x 48" x 56" daylight, 250 tons with heated platens.
Size of flat laminate sheet: Up to 48" x 84".

Type of resins and reinforcements used: polyester, epoxy, & phenolic resins with glass fabrics, mats rovings & chopped fibers.
Type of fabrication: missile and aircraft structural components, containers, and pressure vessels.
Gen. Mgr.—E. A. Speakman
Pur. Agt.—G. J. Ryan
Mgr. Plastics—C. R. Lemonier

American Combining Corp., Rockaway Beach (New Jersey)
Continuous laminating: 20 Mil., cloth.
Type of resins and reinforcements used: vinyl, cellulose.
Personnel: see p. 1106

American Hard Rubber Co., New York
Types of molding done: preform molding, quick molding matched metal steel molds.
Presses: see compression press equipment list.
Type of resins and reinforcements used: glass and cellulosic fibers polyester and phenolics.
Number of preformers: 3 large
Type of fabrication: all normal punching cementing and assembly operations.
Pres.—V. T. Norton
V. Pres. & Sales—Roland Reppert
Pur. Agt.—V. E. Culver

Atlas Plastics, Inc., Buffalo
Types of molding done: contact mandrel wrap, vacuum bag & matched die molding; plaster, wood aluminum and steel molds.
Presses: 6 up to 24" x 24", 20" daylight.
Size of flat laminate sheet made, if any: 24 x 24
Type of resins and reinforcements used: polyester & epoxy (resins), glass fabric, mat and rovings, (reinforcement).
Pres.—H. S. Nathan
V. Pres.—J. H. Nathan
Sales Mgr.—D. L. Thomas

Castle Plastics, Inc., New York
Number and size preformers: 2 stokes model T
Pres. & Sales Mgr.—C. V. Flynn

Cheslam Corporation, Yonkers
Continuous laminating: paper 40" wide, cellophane 40" wide.

Du Verre, Inc., Buffalo
Types of molding done: Tubes, special shapes.
Types of resins and reinforcements used: polyester, epoxy resins, fibrous-glass, Synthetic fiber reinforcements.
Type of fabrication: custom fabrication of duct systems, hoods, tanks, special shapes.
Personnel: see p. 1092

Glasply Corp., Mount Vernon
Types of molding done: convolute tubing-matched dies hand lay-up bag molding.
Presses: 1-18" x 24" press.
Size of flat laminate sheet: 58" max. width x 20 ft. max. length.
Types of resins and reinforcements used: polyester, epoxy, fibrous-glass, paper, premix.
Type of fabrication: machining & assembly to close tolerances.
Personnel: see p. 1092

Herblin Corp., Glen Cove
Types of molding done: hand lay-up. vacuum bag, press fiber glass, epoxy, Aluminum.
Presses: 6-24 x 36, 48 daylight.
Type of resins and reinforcements used: epoxy Polyester, glass, orlon, dacron, sisal.
Type of fabrication: protypes-production runs radomes, boats etc.; specialize in large items.
Pres. & Pur. Agt.—G. B. Herblin
V. Pres.—C. V. Herblin
Sales Mgr.—W. L. Herblin

●**Insulation Manufacturing Co., Inc.,** Brooklyn
Types of molding done: compression & transfer hand, semi-auto and automatic.
Size of flat laminate sheet: 18" x 24" school desk tops melamine surface

Marbek, Inc., Brooklyn
Continuous Laminating: cloth and paper all widths up to about 57" all thicknesses.
Personnel: see p. 1106

Plastic Center, Rochester
Type of fabrication: plexiglas & phenolic fabrication.
Personnel: see p. 1093

Plasti-Vue, Whitestone
Type of fabrication: vacuum forming, blowing, drawing precision machining, forming of sheets.

Rudd Plastic Fabrics Corp., Brooklyn
Types of molding done: press polishing.
Size of flat laminate sheet: 24" x 54"
Continuous laminating: cloth & paper to vinyl 54" wide up to 40 gauge.
Type of resins and reinforcements used: vinyl chloride, styrene copolymers.
Type of fabrication: calendering laminating, embossing, & press polishing and printing
Personnel: see p. 1106

Scheri Process Division of Ferro-co. Corp., Long Island City
Types of molding done: wet lay-up on male or female molds of wood, plaster, metal, reinforced polyester.
Size of flat laminate sheet: 50" x 152" any thickness.
Continuous laminating: 44" wide up to 1/16" thick paper, glass, or cloth.
Type of resins and reinforcements used: polyester & epoxy resins, glass, dynel, cotton, etc.
Type of fabrication: reinforced plastics, wet lay-up and secondary bonding.
Pres.—Kenneth Carroad
V. Pres.—Gunhilde Carroad
Sales Mgr.—Bernard Goldberg
Pur. Agt. & Plant Mgr.—Morton J. Gurdin

Silicone Insulation, Inc., Bronx
Types of molding done: matched metal molding of insulating & other shapes.
Presses: 20 to 40" x 40"
Size of flat laminate sheet: 36" x 36".
Type of resins and reinforcements used: silicone, polyester, epoxy, melamine, phenolic glass cloth Mat, glass fibres.
Type of fabrication: insulating shapes, slot wedges, coil bobbins, core tubes and parts to print.
Pres.—W. Elsfelder
V. Pres. & Sales Mgr.—A. Margosian
Pur. Agt.—D. Singer

Starlite Plastic Co., Kenmore
Types of molding done: compression & hand lay-up plastic plaster & steel mold.
Presses: 3-36" x 72"

●Indicates Advertiser.

Type of resins and reinforcements used: polyester resin, glass flock reinforcement.
Pres.—A. Bonk
V. Pres.—S. Bonk
Sales Mgr. & Pur. Agt.—S. Weir

Superior Laminating Co., New York
Presses: 1 Press 6 x 9 platen, Daylight space 1" on each of 2 platens
Size of flat laminate sheet: 5" x 8"
Type of fabrication: Acrylic-sanding, polishing, drilling, laminating, cutting, spindle carving, internal carving
Personnel: see p. 1093

Syracuse Ornamental Co., Syracuse
Types of molding done: compression matched & metal molds.
Type of resins and reinforcements used: polyester, glass.
Number and sizes of preformers: 1-3 ft. Dia.
Pres.—A. E. Holstein
V. Pres.—P. M. Holstein
Sales Mgr.—R. A. Holstein
Pur. Agt.—M. F. Clark

Syracuse Plastic Molders, Syracuse
Type of fabrication: vacuum forming 1-48" x 96" twin table vacuum forming 1-36" x 24" single.
Pres.—Joseph R. Falcone
V. Pres.—Anthony Falcone, Jr.

TMC Industrial Corp., Mamaroneck
Types of molding done: low and contact pressure, using aluminum, plastic, wood & plaster molds; vacuum bag mold molding; hand lay-up molding.
Type of resins and reinforcements used: polyester, epoxy, glass fiber rovings: mat, and glass cloth.
Type of fabrication: development-prototypes & production of all size products.
Pres. & V. Pres.—W. L. Deans
Pur. Agt.—T. McWaters, Jr.
Mgr. Plastic Div.—A. Mills

United Mask & Nov. Co. Inc., Glendale
Type of fabrication: vacuum forming: 8 machines up to 48 x 96"
Pres.—Elwood Pamatat
V. Pres., Sales Mgr. & Pur. Agt.—Clinton Pamatat

NORTH CAROLINA

Southern Plastics Engineering Corp., Greensboro
Number and sizes of performers: 1—12 ton.

OHIO

Armored Plastics Co., Div. of Globe Wernicke Industries, Inc., Toledo
Type of molding done: mat & preformed molded parts in matched metal molds.
Presses: 1-60" + 84", 4' strokes, 84" daylight, 2-60" + 42", 4' strokes, 7' daylight.
Types of resins and reinforcements used: glass fibers.
Preformers: 2-4", 1-36"
Type of fabrication: molded parts, punch, press & assembly.
Pres.—Wm. D. Hohn
Exec. V. Pres.—Joseph F. Howard
Mgr., Plastics Div.—Robert S. Beverlin
Sec.—Wayne H. Patterson
Pur. Agt.—Walter J. Todd

●Indicates Advertiser.

●**Barren. J. E., Plastics, Inc.,** Cincinnati
No. of Presses, platen area, daylight space: 2 presses, 20x42 area, 2" daylight.
6 platens in one press, 8 in the other.
Size of Lam. Sheet: 20x24.
Resins and reinforcements used: butyrate, wire reinforced.

Baxter Co., Cincinnati
Type of fabrication: acrylic, vinyl acetate co polymer, polyethelene.
Pres. & Treas.—J. E. Baxter
V. Pres. & Secy.—Robert Stern
Pur. Agt.—John Helgesen

Cincinnati Development & Mfg. Co., Cincinnati
Presses: 1-50 ton, 1-30 ton.
Size of flat laminate sheet: 24" x 38", 10½" x 36".
Type of resins and reinforcements used: fibrous-glass, polyester resin.
Type of fabrication: stamping, shearing, drilling, sawing, grinding, milling.
Pres. William H. Mooney
Exec. V. Pres. & Sales Mgr.—William M. Mooney
Pur. Agt.—Edmund D. Mooney

Francis Industries, Pataskala
Types of molding done: press, wet lay-up, premix.
Presses: 6 presses, to 50 tons, special design.
Type of resins and reinforcements used: epoxy, polyester, alkyd, phenolic, glass, nylon.
Type of fabrication: as required.

●**General Tire and Rubber Co.,** Akron
Types of molding done: matched metal molds
Presses: 50 presses: 30" x 30" up to 48" x 108", up to 30" daylight.
Type of resins and reinforcements used: polyester, epoxy, glass, sisal.
Number of sizes of preformers: 5 up to very large.
Type of fabrication: custom
Personnel: see p. 1085

Glastic Corp., Cleveland
Types of molding done: flat sheet and premix.
Presses: 12
Size of flat laminates sheet: 36 x 72".
Type of resins and reinforcements used: polyester, fibrous-glass.

Greene, Ray, & Company, Toledo
Presses: 3-18 x 80, 16 x 16, 12 x 48.
Types of resins and reinforcements used: polyester & epoxy glass & asbestos.
Type of fabrication:
Large objects. (Boats etc. to 40').
Personnel: see p. 1093

Heil Process Equipment Corp., Cleveland
Size of flat laminate sheet: 36" x 96", 48" x 96".
Type of resins and reinforcements used: polyester, glass epoxy glass.
Type of fabrication: industrial equipment ventilating ducts, tanks, trays.
Pres.—C. E. Heil
V. Pres.—E. W. Vereeke
Sls. Mgr.—D. E. Holmgren
Pur. Agt.—G. C. King

Plastic Parts Corp., Maumee
Types of molding done: matched die and vacuum bag, using plastic or metal dies.
Pres.—W. F. Broer, Jr.
V. Pres.—D. L. Lambert, Jr.

Plastic Products Corp., Bedford Heights
Types of molding done: custom molding, matched metal.
Presses: 2 presses with 20" x 20" platen, 18" daylight: 2 with 30" x 36" platen, 30" daylight: 2 with 50" x 50" platen, 36" daylight.
Type of resins and reinforcements used: polyester resin, fiberglass reinforcement.
Number and sizes of preformers: 1-36" preformer, 1-48" preformer, 1-54" preformer.
Personnel: see p. 1105

●**Plastic Research Products,** Div. of **Grimes Mfg. Co.,** Urbana
Types of molding done: compression and transfer.
Presses: 50
Types of resins and reinforcements used: prepared molding compounds (plaskon, Esterine, Glaskyd, etc.)
Number and sizes of preformers: 6 preformers up to 50 ton.
Personnel: see p. 1086

●**Structurlite Plastics Corp.,** Hebron
Types of molding done: glass reinforced plastics, preform, premix and silicone.
Presses: 16 presses: ranging from 25 to 500 ton cap. with platen areas from 2' up to 6' x 6'. Daylight space from 24" to 94".
Type of resins and reinforcements used: polyester and silicone resins. Glass roving and mat.
Number and sizes of preformers: 1-24" automatic, 1-30" automatic, 1-6" dia. turntable and 4-30" dia. turntable.
Type of fabrication: punching, cementing and assembly.
Pres.—Charles D. Jones
V. Pres. & Sales Mgr.—Robert E. Griffith
Pur. Agt.—L. R. Rose

OKLAHOMA

Fibercast Corp., Sand Springs
Types of molding done: pipe fittings, matched die molding, epoxey & polyestine, molding gunks.
Presses: 3-25 ton each, 18" x 18" x 18".
Type of resins and reinforcements used: epoxy, resins and hardners, glass fibers.
Type of fabrication: patented centrefugal casting of pipe & tube 2 3/8" OD, 2 7/8" O. D., 3½" O. D. x 21' lengths. Pipe fabrication to suit.
Pres.—George McCuskey
V. Pres.—Dr. Karl Fetters
Sales Mgr.—Jerry Hutchison
Pur. Agt.—Jack Woods

PENNSYLVANIA

●**American Insulator Corp.,** New Freedom
Types of molding done: press molding, vacuum bag molding, hand lay-up, pre-mix molding-matched metal, single member sheet metal, wood plastic molds.

Presses: 1-40 ton 48" x 72" platen, 72" daylight, 1-80 ton 48" x 78" platen, 72" daylight, 1-100 ton 48" x 48" platen, 108" daylight, 1 turner preformer.
Size of flat laminate sheet made: 36" x 52" in thickness from ¼" to ½".
Types of resin used: polyester, epoxy fiberglass chopped strands, roving, mat, woven cloths, sisal chopped fibers.
Number and size of preformers: 1 turner preformers.
Type of fabrication you do: sawing, routing, grinding, drilling, rivetted and bonded assemblies, silk screening and spray painters.
Personnel: see p. 1087

•Consolidated Molded Products Corp., Scranton
Types of molding: reinforced glass fiber, steel and aluminum matched metal molds.
Presses: 8 low pressure presses up to 200 tons: up to 60" x 84" platen: 84" daylight.
Personnel: see p. 1087

Curry Arts Molding & Laminating Co., Scranton
Types of molding done: compression molding, chromium plated stainless steel molds.
Presses: One; area 36" x 38", 4 openings, 3½" daylight ea. opening.
Size of flat laminated sheet: 21 x 25½".
Type of fabrication: forming, machining, assembling, etc.
Personnel: see p. 1087

•Erie Plastics Co., Div. of Erie Iron & Supply Corp., Erie
Presses: 1-4½", 1-2", 1-3¼
Type of fabrication: reprocessing and pelletizing of thermoplastic materials; also custom extrusion.
Pres., Sales Mgr. & Pur. Agt.—Edward A. Zacks

Halsey, Inc., Scranton
Types of molding done: compression & transfer.
Pres., Sls. Mgr. & Pur. Agt.—Halsey J. Sorrell
V. Pres.—C. W. Hupfer

Hays Mfg. Co., Erie
Types of molding done: compression.
Size of flat laminate sheet: 36" x 48".
Type of resins and reinforcements used: (polyester, phenolic, epoxy) glass, cloth, etc.
Pres.—W. H. Forster
V. Pres.—J. D. Clemens
Sls. Mgr.—H. H. Clemens

McClarin Plastics, New Oxford
Types of molding done: low pressure laminates hand lay-up.
Type of resins and reinforcements used: polyester resin, glass reinforcement.
Type of fabrication: products from plexiglas.
Pres. & Pur. Agt.—C. G. McClarin
V. Pres. & Sales Mgr.—R. G. Meckley

Mechtronics, Philadelphia
Types of molding done: hand lay-up & Vacuum Bag
Size of flat laminate sheet: 4 x 12 ft.

Type of resins and reinforcements used: polyester, epoxy, resins, glass & misc. reinf.
Pres.—Semond Levitt

Molded Fiber Glass Tray Co., Linesville
Types of molding done: compression molding matched metal molds.
Presses: 14 presses: 1-40" x 48", 61" daylight: 9-32" x 36, 38" daylight: 4-20" x 20", 28" daylight.
Types of resins and reinforcements used: polyester resin, fiberous-glass & sisal reinforcements.
Type of fabrication: materials handling trays, boxes, wire spools and pallets.
Pres. & Pur. Agt.—A. W. Levenhagen
V. Pres. & Sales Mgr.—J. W. Moore

• Perry Plastics, Inc., Erie
Types of molding done: steel and aluminum molds, pre-mix and mat molding.
Presses: 1-36" x 24", 24" daylight: 1-24" x 20", 20" daylight: 1-48" x 48", 30" daylight.
Size of flat laminate sheet: 48 x 48
Type of resins and reinforcements used: polyester, phenolic resins, fiberous-glass and sisal reinforcements.
Pres.—Jerry V. Stokes
V. Pres. & Treas.—H. H. George
Sales Mgr.—S. C. Seley
Pur. Agt.—H. K. Siegmund

Raybestos-Manhattan, Inc., Reinforced Plastics Dept., Manheim
Types of molding done: compression molding using matched metal molds.
Presses: variety of presses ranging from 6" x 6" up to 3 ft. x 3 ft. with 3 ft. daylight space.
Type of resins and reinforcements used: asbestos & glass reinforcements with phenolic, silicone, epoxy and polyester.
Type of fabrication: flat to complex parts where high strength and extreme heat resistance are required.
Pres.—J. F. D. Rohrbach
V. Pres.—O. H. Cilley
Product Mgr.—D. V. Rosato
Pur. Agt.—W. R. Bitzer

Resolite Corporation, Zelienople
Types of molding done: low pressure, corrugated Al molds.
Size of flat laminate sheet: max. size 42" x 12'.
Type of resins and reinforcements used: polyester and fiberous-glass mat.
Type of fabrication: polyester fiberous-glass reinforced translucent sheets.
Pres.—Elwin G. Smith
Exec. V. Pres.—Kenneth H. Beer
Sales Mgr.—Bernard E. Magette
Pur. Agt.—Joseph Morgan

• Scranton Plastic Laminating Corp., Scranton
Presses: 20" x 25; 36" x 48"; 50" x 108".
Size of flat laminate sheet: same as press sizes above.
Type of resins and reinforcements used: vinylite, acetate, butyrate, polyethylene, acrylic, PVC and styrene. Glass etc.
Personnel: see p. 1107

Sealview Plastics, Inc., Wayne
Types of molding done: custom molding, press, bag and hand lay-up.
Presses: 3-100 ton, 30 x 40 platen, 60" daylight: 1-100 ton, 38 x 72, 10" daylight; 1-50 ton, 30 x 30, 40" daylight.
Size of flat laminate sheet: up to 38" x 120".
Type of resins and reinforcements used: polyesters and epoxies.
Number and sizes of preformers: 1-4' x 5', 1-6' x 6'.
Type of fabrication: corrugated step-lap, decorative architectural, large small-run structures, prototypes
Pres.-Robert C. Watson
V. Pres. & Treas.—High H. Aiken

Strick Plastics, Perkosie
Types of molding done: compression, hand lay-up.
Presses: 1-65" x 105", 14"; 2-12" x 12", 20"; 1-18" x 116", 24"
Size of flat laminate sheet: 50" x 100" thickness 1/32 to 2".
Type of resins and reinforcements used: polyester resins, glass cloth & glass mat.
Type of fabrication: punch, shear, drill, rout, grind.
Personnel: see p. 1093

Synthane Corp., Oaks
Types of molding done: compression.
Presses: Over 50 of many sizes & types.
Size of flat laminate sheet: 005" to 8" thick, 36" x 36", 72" x 36", 96" x 24".
Types of resins and reinforcements used: phenolics, melamine, epon-silicone, dap cellulose paper & fabric-glass, fabric glass mat, cotton mat, asbestos paper and fabric, orlon, nylon fabrics.
Number and sizes of preformers L 2
Type of fabrication: complete facilities for complete fabrication service
Personnel: see p. 1093

Washington Plastics Co., Sharon
Presses: 1.
Size of flat laminate sheets: 8 x 10.
Whether glass, paper or cloth, paper-cloth, etc.
Type of laminating: pictures on wood or paper, etc.
Personnel: see p. 1093

RHODE ISLAND

Anchorage Plastics, Inc., Warren
Types of molding done: fiberglass prepreg. mat and cloth polyester.
Presses: 30 x 36 platen, 50 ton 2 ft. daylight adjustable pyrometer heat control electric heater steel molds.
Type of resins and reinforcements used: mat pre-preg and glass cloth polyester resins.
Type of fabrication: hand lay-up and compression also vac press molding.
Personnel: see p. 1088

TENNESSEE

National Plastics, Inc., Knoxville
Types of molding done: reinforced preimpregnated glass mat with matched molds.
Presses: 2-26" front to back, 31" left to right, 47" daylight; 2-25" front to back, 26" left to right 36" daylight; 2-24" front to back, 25" left to right 24" daylight.
Pres.—Chris Van Deventer, III
V. Pres. in charge of Sales—Charles L. Yeomans
V. Pres. in charge of operations—M. T. Victor

•Indicates Advertiser.

TEXAS

Lone Star Plastics Co. Inc., Fort Worth
Types of molding done: high and low pressure matched die molding, bag molding, contact lay-up. All type molds used.
Presses: 1-30" x 48" x 18"; 1-12" x 18" x 18"; 1-40" x 60" x 14"; 1-12" x 15" x 18"; 1-24" x 24" x 20"; 2-8" x 10" x 10".
Size of flat laminate sheet: 48" x 144".
Type of resins and reinforcements used: polyester & epon resins with fibrous-glass; also silicone & resins & silastic.
Type of fabrication: do all types low pressure bag or contact molding with wet lay-up or preimpregnated materials. Specialize in industrial applications.
Pres.—Melvin Hare
V. Pres.—E. H. Swazey

Polymer Engineering Corp., Houston
Types of fabrication: contact pressure and bag molded laminates with polyester and epoxy resins, glass and other reinforcements.
Pres.—John Belding
Vice Pres. & Gen. Mgr.—R. P. Bailey
Sec. & Treas.—R. H. Hughes
Pur. Agt.—Alexander Brown

Texas Glass Fiber Corp., Grandview
Types of molding done: boat hulls, hand lay-up, plastic molds.
Type of resins and reinforcements used: polyester, glass fiber.
Pres.—W. E. Hutton-Miller
V. Pres.—Charles E. Martens
Pur. Agt.—W. C. Ward

VERMONT

Newport Plastics Corporation, Newport
Types of molding done: low pressure with special collapsible molds of metal, plastic etc.
Presses: 17 special designed presses.
Type of resins and reinforcements used: polyester, epoxies, and polyurethane.
Type of fabrication: insulated cold food containers for airlines.
Pres.—J. R. Audet
Pur. Agt.—Paul Beaudry & Lloyd Douglas

VIRGINIA

Hafleigh & Company, Buchanan
Types of molding done: steel-matched.
Type of resins and reinforcements used: polyesters.

Universal Moulded Products Corp., Bristol
Types of molding done: metal molds used autoclave molding, vacuum blanket molding, matched metal die molding, compression molding.
Presses: see compression presses in first column.
Type of resins and reinforcements used: polyesters, phenolics, silicones and epoxies, reinforcement; glass or asbestos fibers or cloth, and mats.
Number and sizes of preformers: 1-36", 1-72".
Type of fabrication: autoclave molding, vacuum blanket molding, matched metal die molding, compression molding, tube rolling, machining.
Personnel: see p. 1089

WASHINGTON

A & B Plastics, Seattle
Type of resins and reinforcements used: epoxy & polyester
Type of fabrication: custom body & boat repairs
Pres., Sales Mgr. & Pur. Agt.—C. A. Weaver, Jr.

Allied Mfg. Co., Seattle
Types of molding done: all types glass reinforced molding steel molds.
Presses: 2-300 T., 32" x 36" platen 24" daylight
Pres.—C. A. Stone
V. Pres. & Treas.—B. Wallace

Everlite Corp., Seattle
Types of molding done: continuous laminating, flat and corrugated, also special shapes.
Size of flat laminate sheet: 45" x 144".
Continuous laminating: 45" x ⅛" thick max. glass cloth & mat also special combinations.
Type of resins and reinforcements used: polyester glass-rayon, cloth paper.
Type of fabrication: proprietory skylites & suspended ceiling systems.
Pres.—Robert H. Anderson
V. Pres. & Pur. Agt.—Alva L. Strope
Sales Mgr.—Kenneth R. Anderson

Pacific Plastics Co. Inc., Seattle
Types of molding done: hand lay-up of duct of any shape
Presses: 28 x 28-4' daylight 100 ton; 36 x 40-5' daylight 150 ton; 48 x 96 - 200 ton; 6' daylight; 30 x 48-30" daylight 200 ton.
Size of flat laminate sheet: to order.
Continuous laminating: mfg. tank boats-printed circuits, etc.
Types of resins and reinforcements used: all types.
Number and sizes of preformers: can handle 48 x 48" x 48 preform.
Personnel: see p. 1089

WISCONSIN

Northern Plastics Corp., La Crosse
No. of presses, platen area, and daylight: 4 presses
Size of flat lam. sheets: 39" x 47", 39" x 41"
Whether paper, glass or cloth: all three.
Fabrication: all laminated and post formed laminated parts.
Sales Mgr.—Ray B. Haugen

Lewis, G. B., Company, Watertown
Types of molding done: matched metal dies of meehanite, forgings and tool steel, custom molding of preform and premixed parts.
Presses: 8 from 5 to 250 tons, up to 48" x 96", 84" daylight, 66" stroke.
Type of resins and reinforcements used: polyester and epoxy resins, glass fiber and asbestos reinforcements.
Number and sizes of preformers: 6
Type of fabrication: custom and proprietary products.
Pres.—G. Gordon Frater
V. Pres. & Sls. Mgr.—Milton A. Frater
Pur. Agt.—Arthur J. Killian

Weber Plastics, Inc., Stevens Point
Types of molding: expandable polystyrene, special molds designed for above process.
Presses: 1-24" x 24", 20" daylight, 1-10" x 20", 14" daylight
Pres.—E. C. Wotruba
V. Pres.—M. E. Sorensen

ENGLAND

●**Microcell, Ltd.,** London
Types of molding done: hand lay-up, rubber bag, matched tool.
Presses: 3 large, presses : 8' x 4' with 8' daylight.
Size of flat laminate sheet: up to 8' x 4'.
Continuous Laminating: 6' wide x 1/8" thick, glass fiber.
Type of resins and reinforcements used: polyester, epoxides, phenolic glass cloth, mats, asbestos, cellulonics.
Number and size of preformers: 3 up to 20 sq. ft. preform area.
Personnel: see p. 1094

NOTICE

Despite every effort of the editors to make this Directory Section as complete and authoritative as possible, some companies which should be listed have, we feel sure, been overlooked. In January, 1958, preparation of the Directory Section for the 1957 Modern Plastics Encyclopedia Issue will get under way, and if you want your company to be included, the time to do something about it is *right now*.

Listings in the Directory Section are restricted to manufacturers of plastics chemicals and materials, to machinery and equipment manufacturers, and to businesses performing *custom* services—such as moldmakers, molders, laminators, fabricators, film processors, and the like.

If your company was listed this year, you will automatically receive a listing sheet for the 1958 Directory Section. If your company falls into one of the categories mentioned above and was *not* listed this year, write today and ask that a listing sheet be sent you. Please remember that we will not mail 1958 listing sheets before January 15, 1958.

Directory Editor

MODERN PLASTICS ENCYCLOPEDIA ISSUE

575 Madison Avenue New York 22, N. Y.

Complete addresses of companies listed appear on pp. 1123-1149

DIRECTORY OF TRADE DESIGNATIONS OF PLASTIC MATERIALS AND PROCESSES

This list of trade designations is compiled for reference purposes from information supplied to us by the companies concerned. The descriptive information, however, is not guaranteed although, with a few exceptions, each of the trade designations was accompanied by a registration number and date. For complete addresses, refer to alphabetical list, page 1123.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
	A	
A-C Polyethylene	Low-molecular-weight polyethylene	Semet-Solvey Petrochemical Division, Allied Chemical and Dye Corp., N.Y., N.Y.
A-M	Adhesives, resins, chemicals, etc.	American-Marietta Co., Adhesive, resin & Chemical Division, Seattle, Washington
Acco	Polymers, copolymers of acrylic & methacrylate esthers. Specialty-private formulas	Acco Polymers, New York, New York
AccuRay	Industrial beta gauges used in measuring the weight, thickness, and area of sheet materials.	Industrial Nucleonics Corp., Columbus, Ohio

Acrocut	Letter Cutting In Molds or Dies	Acromark Co., Elizabeth, N.J.
Acrodie	Precision Dies	Acromark Co., Elizabeth, N.J.
Acrograve	Metal and Plastic Engraving	Acromark Company, Elizabeth, N.J.
Acrohex	Electric Branders for Plastic, Wood, Fibre.	Acromark Company, Elizabeth, N.J.
Acromark	Marking & Numbering Machines	Acromark Co., Elizabeth, N.J.
Acromarker	Name Plate Stamping Machines	Acromark Co., Elizabeth, N.J.
Acronal	Polymers of acrylic esters and mixed polymers in the form of acqueous dispersions and solutions.	Badische Anilin- & Soda Fabrik A. G., Germany
Acroprene	Synthetic Rubber Dies	Acromark Company, Elizabeth, N.J.
Acroprinter	Parts Printing Machines	Acromark Co., Elizabeth, N.J.
Acrostamp	Stamps for Marking Plastic, etc.	Acromark Co., Elizabeth, N.J.
Acrotool	Marking & Engraving Tool	Acromark Co., Elizabeth, N.J.
Acrotype	Precision Stamping Type	Acromark Co., Elizabeth, N.J.
Acrylon	Rubber	Borden Company, Chem. Div., New York, N.Y.
Ad-Ons	Vacuum formed designs to be applied to larger plastic items.	W. L. Stensgaard and Associates, Inc., Chicago, Ill.
Adipol	Plasticizers-adipate esters.	Ohio-Apex Div. F.M.C., Nitro, W. Va.
Advastab	Heat and Light Stabilizers for Chlorinated Resins.	Advance Solvents and Chemical, Div. of Carlisle Chemical Works, Inc., New Brunswick, New Jersey
Advawet	Additive-Viscosity Depressent	Advance Solvents and Chemical, Div. of Carlisle Chemical Works, Inc., New Brunswick, New Jersey
Aer-O-Buoy	Polyvinyl chloride foams	Robinson Moulded Products, Ltd., Toronto, Ontario, Canada
Aeroflex	Polyethylene Extrusions	Anchor Plastics Co., Long Island City, N.Y.
Agilene	Polyethylene semi-finished components (sheet, rod, tube, bar, etc.)	American Agile Corp., Maple Heights, Ohio
Agilide	Non-plasticized polyvinyl chloride semi-finished components	American Agile Corp., Maple Heights, Ohio
Air-Clamp	Air Cylinders	Mead Specialties Co., Inc., Chicago, Illinois
Aircomb	Impregnated Kraft Honeycomb	Douglas Aircraft Co., Inc., Santa Monica, Calif.
Airmatic	Air valves, air cylinders, hydraulic valves and hydraulic cylinders	Airmatic Valve, Inc., Cleveland, Ohio
Aldorome	Odorants for Formaldehyde	Fritzsche Brothers, Inc., New York, New York
Alfane	Epoxy based cement	The Atlas Mineral Products Co., Mertztown, Penna.
Alkonex	Polyester coating materials	General Electric Co., Chemical Materials Dept., Pittsfield, Massachusetts
Alker	Furan resin cement	The Atlas Mineral Products Co., Mertztown, Penna.
Alipal	Surface active agent; antistatic agent	Antara Chemicals, Division of Aniline & Film Corp., New York, New York
Alk-O-Flex	Plasticizers, low temperature laminating resins, heat and light stabilizers	Alkydol Laboratories, Inc., Cicero 50, Illinois
Alk-O-Mer	High polymer emulsions	Alkydol Laboratories, Inc., Cicero 50, Illinois
Alpex	Hydrocarbon resins	Alkydol Laboratories, Inc., Cicero, Illinois
Alundum	Abrasives, Grinding Wheels, Refractories	Norton Co., Worcester, Mass.
Airborne	Expanded Plastic (urethane foam)	Albert Trostel & Sons Co., Airborne Division, Milw., Wis.
Airoyal	Air cylinders, hydraulic cylinders, hydraulic power units	The Airoyal Co., Maplewood, New Jersey
Akroflex	Rubber Antioxidants	E. I. du Pont de Nemours & Co., Inc., Polychemicals Dept., Wilmington, Delaware
Alathon	Polyethylene resin, molding compounds	E. I. du Pont de Nemours & Co., Inc., Polychemicals Dept., Wilmington, Del.
Alchemick	Alkyd Enamel Interior or Exterior	Triacon Laboratories Division, Devoe and Raynolds Co., Inc., Detroit, Michigan
Alkanol	Surface Active Agents	E. I. du Pont de Nemours & Co., Inc., Polychemicals Dept., Wilmington, Delaware
Alperox C	Organic Peroxide type Catalysts	Lucidol Div., Wallace & Tiernan, Inc., Buffalo, N.Y.
Amco Plastic Pipe	Plastic pipe	Amco Plastic Pipe Co., San Leandro, California
Ameron	Liquid Dispersions of Plastic Materials	B. F. Goodrich Co., Akron, Ohio
Amercoat	Protective coatings	Amercoat Corp., South Gate, Calif.
Amester	Polyester resins	American Alkyd Industries, Carlstadt, New Jersey
Ampacet	Thermoplastic Molding Compounds	American Molding Powder & Chemical Corp., Brooklyn, N.Y.
Amphosive	Series of adhesives for industrial use.	Atlas Mineral Products Co., Mertztown, Penna.
Ampreg	Polyester resin coating	The Atlas Mineral Products Co., Mertztown, Penna.
Amres	Phenolic, Resorcinol, Urea Resins	American-Marietta Co., Adhesive, Resin & Chem. Div., Seattle, Washington
Analyte	Color comparator	Crown Engineering and Sales Co., Harrison, N.J.
Anesite	Thermoplastic Pipe Tubing, and other Cross-Sections	Anesite Co., Chicago, Illinois

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Anesite	Extruded thermoplastic products	Anesite Co., Chicago, Illinois
Ansol	Denture alcohol solvent	U.S. Industrial Chemicals Co., Div. National Distillers and Chemical Corporation, New York, New York
Anstol C	Anti-Static Agents	Chemical Development Corp., Danvers, Mass.
Antamx	Surface active agent; dispersant in cellophane mfg.	Antara Chem., Sales Div. of Gen. Aniline & Film Corp., New York, N.Y.
Antox	Rubber Antioxidants	E. I. du Pont de Nemours & Co., Inc., Polychemical Dept., Wilmington, Delaware
Aquablak	Carbon Black dispersed in water	Columbian Carbon Co., New York, N.Y.
Aquarex	Mold lubricant	E. I. du Pont de Nemours & Co., Inc., Polychemicals Dept., Wilmington, Del.
Aquarex	Surface Active Agent	E. I. du Pont de Nemours & Co., Inc., Polychemicals Dept., Wilmington, Delaware
Aquatel	Moisture gauge	Isotope Products, Buffalo, New York
Arabol	Adhesives	The Arabol Mfg. Co., New York, New York
Archer	Self-adhesive Labels and Label Dispensers	Archer Label Company, Los Angeles, California
Arcturus	Colorants (red)	The Sherwin-Williams Co., New York, New York
Ariteno	Epoxy resin formulations	Aries Laboratories, Inc., New York, N.Y.
Armorhide	Textured plastic finish resembling leather for use on metal, plastics, etc.	John L. Armitage & Co., Newark, N.J.
Armor	Vinyl and polyethylene film and sheeting	Ross & Roberts Co., Stratford, Conn.
Astralon	Vinyl chloride polymer	Dynamit-Actein-Gesellschaft Troisdorf, W. Germany
Atlac	Solid Polyester Resin	Atlas Powder Co., Wilmington, Delaware
Atlastasol	Vinyl plastisol	Atlas Mineral Products Co., Mertztown, Pennsylvania
Ase	Antiskinning agent	National Aniline Division, Allied Chemical & Dye Corporation, New York, 6, N.Y.
Asp	Mineral Filler	Minerals & Chemicals Corp. of America, Menlo Park, New Jersey
Auto-Tap	Lead screw tapping heads and attachments and automatic tapping machines	Automatic Methods, Inc., Elizabeth, New Jersey
Aviaco	Urea-formaldehyde molding compounds	American Viscose Corporation Philadelphia, Pennsylvania
Avitex	Surface Active Agents, Softeners, Antistatic Developer.	E. I. du Pont de Nemours & Co., Inc., Polychemicals Dept. Wilmington, Delaware
Bakelite	Phenolic, polystyrene, polyethylene, Fluorothene, vinyl chloride, vinyl acetate, vinyl butyral, polyester, and epoxy resins; molding materials; extrusion compounds; sheeting and film; rigid sheets; laminating varnishes for high-, low-, and contact-pressure laminated plastics; laminating compounds; synthetic resins for paints and varnishes; resins for baking and surface coatings; resins for impregnating, calendering, and bonding; resin wood glues; technical cements; and resins for adhesives.	Bakelite Co., a Div. of Union Carbide & Carbon Corp. New York, N.Y.
Banbury	Mixers	Farrel-Birmingham Co., Inc. Ansonia, Conn.
Bandsander	Belt sander	Mead Specialties Co., Chicago, Ill.
Barak	Accelerator Activator	E. I. du Pont de Nemours Co., Inc., Poly chemical Div., Wilmington, Del.
Barco	Stabilizers	Deecy Products Co., Cambridge, Mass.
Barco	Joints: flexible, swivel, swing and revolving	Barco Manufacturing Co., Barrington, Illinois
Bar-Ox	Aklyd Steel Paint	Truscon Labs., Div. of Devoe & Reynolds Co., Inc. Detroit, Michigan
Beckamine	Alcohol soluble urea, Formaldehyde resins	Reichhold Chem., Inc., White Plains, New York
Beckerley	Precision Weights	The Torsion Balance Company Clifton, New Jersey
Beckolin	Synthetic oils	Reichold Chem., Inc., White Plains, New York
Beckopol	High melt point modified phenolic resins	Reichhold Chem., Inc., White Plains, N.Y.
Beckosol	Alkyd resins	Reichhold Chem., Inc., White Plains, N.Y.
Balcabalsa	Core Material for RP	Balsa Ecuador Lumber Corp., New York 36, N.Y.
Beetle	Urea-formaldehyde molding material	American Cyanamid Co., Plastics and Resins Div., New York, N.Y.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Benvic	Vinyl Chloride and Vinyl acetate chloride compounds.	S. A. Solvic, Brussells, Belgium
Betacoater	Beta gauge for coaters	Isotope Products, Buffalo, New York
Betameter	Beta gauge	Isotope Products, Buffalo, N.Y.
Bi-Line	Two flexible Polyethylene Pipes continuously joined for Jet Well installations.	Skyline Industries, Skyline Plastic Pipe, Inc., Skyline Plastic Molding, Inc., Titusville, Pennsylvania
Binac	Time-cycle controller	Taylor Instrument Companies, Rochester, New York
Bipel	Presses Compression,-Hydraulic Pelleging Machines,-Power units-hydraulic,-Hydropneumatic Accumulators-Presses-transfer molding,-Controllers - temperature, - Press Platens-electric-induction heated.	B. I. P. Engineering Limited, Sutton Coldfield, Warwickshire, England
Bi-Therm	Bi-Metalic industrial thermometers	Taylor Instrument Companies, Rochester, New York
Black-Buty	Plastic pipe and pipe fittings	Anesite, Company, Chicago, Illinois
Black Pearls	Pelleted channel carbon blacks	Godfrey L. Cabot, Inc., Boston, Mass.
Black-Poly	Polyethylene Pipe & Tubing	Anesite Co., Chicago, Illinois
Blend-oxo	Wetting Agent	Gering Products, Inc., Kenilworth, New Jersey
Boltaflex	Supported & unsupported flexible vinyl sheeting	Bolta Co., Inc., Lawrence, Mass.
Bolta-Quilt	Quilted plastic films	Bolta Co., Inc., Lawrence, Mass.
Baltaron	High-impact, low-pressure moldable plastic (a copolymer)	Balta Co., Inc., Lawrence, Mass.
Bonar	Cellulosic boning (extruded)	Anchor Plastics Co., Inc., Long Island City 6, N.Y.
Bonate	Structural Articles made with reinforced resins	Carl N. Bettle Plastics Corp., Fall River, Massachusetts
Bonding Agent	Metal to Metal Adhesive, Epoxy metal adhesive	Carl H. Biggs Co., Inc., Los Angeles, Calif.
Bondmaster	Industrial adhesives for plastics and metals	Rubber and Asbestos Corporation, Bloomfield, New Jersey
Bontex	Shade cloth, plastic coated	Columbus Coated Fabrics Corp., Columbus 16, Ohio
Bostilm	Vinyl plastic in sheet form, coated with adhesive	B. B. Chemical Co., Cambridge Massachusetts
Bostape	Adhesive coated reinforcing tape	B. B. Chemical Co., Cambridge, Massachusetts
Bostik	Adhesive	B. B. Chemical Co., Cambridge, Massachusetts
Brighton Leaf	Roll leaf	Griffin, Campbell, Hayes, Walsh, Inc., New York, New York
Broncho	Composition supported vinyl	Textileather Div., The Gen. Tire & Rubber Co., Toledo, Ohio
Brushmaster	Paintbrush setting compounds	Rubber & Asbestos Corp., Bloomfield, New Jersey
Butacite	Polyvinyl butyral sheeting	E. I. du Pont de Nemours & Co., Inc., Polychemicals Dept., Wilmington 98, Del.
Butvar	Polyvinyl butyral resins	Shawinigan Resins Corp., Springfield, Mass.
	C	
C.D.	Products made by Chemical Dev. Corp. Lubricants, Adhesives, Coatings, etc.	Chemical Development Corp., Danvers, Mass.
Cabflex (line)	Plasticizers	Godfrey L. Cabot, Inc., Boston, 10, Mass.
Cab-O-Sil	Colloidal Silica-Thickening, Thixotropic, Suspension, Dispersing Agent	Godfrey L. Cabot, Inc., Boston, Massachusetts
Cadco	Cast acrylic rods and tubes-cements, polishes, adhesives-acrylic general purpose; fast setting; monomer and monomer polymer cements and adhesives-bodied adhesives for acetates, styrenes, vinyls-formed plastics & bodies adhesives & solvent adhesives for vinyls to vinyls & vinyls to dissimilar materials, also bodies adhesives for nylon and phenolics. Anti-static polishes for acrylics, vinyls, etc.	Cadillac Plastic Co., Detroit, Michigan
Cadox	Organic Peroxide Catalysts	Cadet Chemical Corp., Burt, N. Y.
Calcerite	Amino-resin casting compound	Furance Plastics, Inc., Los Angeles, California
Calvinac	Vinyl based air dry coatings in colors	James Lithgow Co., Inc., Torrance, Calif.
Calvoseal	Masonry sealant	Lithgow Chemicals Co., Div. of Reinhold Engineering & Plastics Co., Norwalk, California
Calwhite	Natural calcium carbonate extender water ground from White Georgia Crystalline Marble.	The Calcium Products Division, The Georgia Marble Co., Tate, Georgia

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Campco	Thermoplastic sheet and film	Campco Div., of Chicago Molded Products Corp., Chicago, Ill.
Caprocyl	Dyes	E. I. du Pont de Nemours Co., Inc., polychemical div.—Wilmington, Del.
Carbasol	Modified Rosin Esters	C. J. Osborn Co., Linden, New Jersey
Carbolac	High Color, channel carbon blacks	Godfrey L. Cabot, Inc., Boston, Mass.
Carbowax	Polyethylene glycols	Carbide and Carbon Chemicals Co., New York, N.Y.
"Carver Press"	Hydraulic Laboratory Press	Fred S. Carver, Inc., Summit, New Jersey
Cascomite	Powdered synthetic resin adhesives	The Borden Co., Chemical Div., New York, New York
Casco	Glues and adhesives	The Borden Co., Chemical Div., New York, New York
Cascola	Label glue	The Borden Co., Chemical Div., New York, New York
Cascolac	Aqueous casein coating solutions	The Borden Co., Chemical Division, New York, New York
Cascophen	Glues	The Borden Co., Chemical Div., New York, New York
Cascorez	Resin glue	Borden Co., Chemical Div., New York, New York
Cascote	Synthetic resin	The Borden Co., Chemical Div., New York, New York
Castaloy	Clamps, laboratory	Fisher Scientific Co., Pittsburgh, Pennsylvania
Celanese	Acetate film, sheeting, molding material, polyethylene film, sheeting, rigid sheeting, polyester resins, polyvinyl acetate emulsions.	Celanese Corp. of America, Newark, New Jersey
Celanthrene	Dyes	E. I. du Pont de Nemours Co., Inc., Polychemical div., Wilmington, Delaware
Celite	Diatomite products-filter aids and mineral fillers	Johns-Manville, New York, N.Y.
Cellon	Cellulose Acetate with Plasticizers.	Dynamit-Actien-Gesellschaft, Troisdorf, W. Germany
Cellosize	Hydroxyethyl cellulose	Carbide & Carbon Chemicals Co., New York, N.Y.
Celogen	Nitrogen blowing agent for plastics and rubber.	Naugatuck Chemical Division, U.S. Rubber Co., Naugatuck, Connecticut
Celoron	Electrical insulating material	Continental-Diamond Fibre Division of The Budd Co., Inc., Newark, Del.
Cenco McLeod Gages	High Vacuum Gages	Central Scientific Co., Chicago, Ill.
Century Brand	Fatty acids	Harchem Division, Wallace & Tiernan Inc., Belleville, New Jersey
Ceramicon	Capacitors	Erie Resistor Corp., Erie, Pennsylvania
Cerama	Thermocouple wire	Thermo Electric Co., Inc., Saddle Brook, New Jersey
Certus	Vinyl resins	Monite Waterproof Glue Co., Minneapolis, Minn.
Chainomatic	Analytical Balances	The Torsion Balance Co., Clifton, New Jersey
Chemelec	Teflon with additives to alter properties for special applications in process industry and electronic field	United States Gasket Co., Camden, New Jersey
Chemiseal	Teflon gaskets—packing special fabricated items generally required by chemical & process industry	United States Gasket Co., Camden, N.J.
Chemigum	Butadiene/acrylonitrile rubbers	The Goodyear Tire & Rubber Co., Akron 16, Ohio
Chemigum Latices	Butadiene/acrylonitrile copolymer latices	The Goodyear Tire & Rubber Co., Akron, Ohio
Chemlon	Fabricated teflon products	Crane Packing Co., Morton Grove, Ill.
Chem-o-glas	Glass fiber reinforced building panels	Chemold Co., Santa Monica, California
Chem-o-sol	Dispersions of high molecular weight, vinyl chloride polymer, or copolymer, resins in liquid plasticizers—compounds for molding, spreader coating, die wiping, extrusions, dipping, and spraying.	Chemical Products Corp., East Providence, Rhode Island
Chemrok	Chemical resistant plastics for electroplating apparatus & parts thereof, as for other chemical resistant parts	The Richardson Co., Melrose Park, Illinois
Chiksan	Ball-bearing swivel Joints and rotating Joints	Chiksan Co., Brea, Calif.
The Chilton Process	For: Mechanically inlaying articles of manufacture with designs and figures made of metal	Plastic Inlays, Inc., Summit, New Jersey
Chlorowax	Chlorinated Paraffin Wax	Diamond Alkali Co., Cleveland, Ohio
Christian Becker	Analytical Balances	The Torsion Balance Company, Clifton, New Jersey
Chromacyl	Dyes	E. I. du Pont de Nemours Co., Inc., Polychemical Div., Wilmington, Delaware
Chromcote	Chrome colored vacuum metallized finish.	The Eyelet Specialty Co., Waterbury Conn.
Chromolox	Electric Heating Equipment	Edwin L. Wiegand Co., Pittsburgh, Pennsylvania
Cincinnatus	Heavy duty double arm mixers	J. H. Day Co., Cincinnati, Ohio
Clapco	Radiant heaters, immersion heaters	Cleveland Process Co., Cleveland, Ohio
Clopane	Clear vinyl packaging film, heat sealable and printable	Clopay Corp., Cinn., Ohio
Co Ros Co	Corrosion resistant coatings	Cordo Chemical Corp., Norwalk, Conn.
Coblak	Carbon Black Dispersions	Columbian Carbon Co., New York, New York
Coathiokblak	Carbon Black Dispersions	Columbian Carbon Co., New York, New York
Collacral	Thixothropic agent for dispersions and for the production of specialty adhesives.	Badische Anilin- & Soda Fabrik A. G., Germany
Colorite Buttons	Dyeing of plastic parts and/or buttons	Colorite Buttons, New York, New York
Col-o-Vin	Vinyl coated fabric & vinyl unsupported sheeting	Columbus Coated Fabrics Corporation, Columbus, Ohio
Colton	Complete line of machines	Arthur Colton Co., Detroit, Michigan
Computreater	Single end tire cord laboratory unit	C. A. Litzler Co., Inc., Cleveland, Ohio
Conductex	Conductive compounds (electrical)	H. V. Hardman Co., Inc., Belleville, New Jersey
Conoco	Secondary plasticizer for PVC Resin Formulations	Continental Oil Co., Petrochemical Dept., New York, New York
Conolite	Conolite laminates are all based on polyester resins and are provided in both decorative and industrial types. Decorative types are utilized mainly as surface coverings in the traditional manner and are particularly adaptable to the "Do-it-yourself" trade. Our industrial laminates include electrical grades, fuel cell backing board, general purpose aircraft construction board and sign board.	Continental Can Company, Inc., Wilmington, Delaware
Contact	Self-adhesive labels	Archer Label Co., Los Angeles, California
Continental	Carbon black	Witco Chemical Co., New York, New York
Continex	Carbon black	Witco Chemical Co., New York, N.Y.
Cordfil	Random cut cotton, rayon or nylon cord	The Rayon Processing Co. of R. I., Pawtucket, Rhode Island
Cordo	Laquer coatings for bonding, laquer coatings for plastic sheeting	Cordo Chemical Corp., Norwalk, Conn.
Cordobond	Special purpose adhesives	Cordo Chemical Corp., Norwalk, Conn.
Cordocled	Corrosion resistant paints	Cordo Chemical Corp., Norwalk, Conn.
Cordoflex	Protective coatings	Cordo Chemical Corp., Norwalk, Conn.
Cordoglas	Plastic resins & compounds for impregnating	Cordo Chemical Corp., Norwalk, Conn.
Cordopreg	Polyester reinforced fibreglas	Cordo Chemical Corp., Norwalk, Conn.
Cordotack	Tacky adhesives	Cordo Chemical Corp., Norwalk, Conn.
Coresinblak	Carbon Black Dispersions	Columbian Carbon Co., New York, New York
Corpolin	Industrial humectant or paper plasticizer	Heyden Chem. Corp., New York, N.Y.
Cosmos & Cosmos-Chrome	Electronic sealing machines and parts thereof.	Cosmos Electronic Machine Corp., New York, New York
Cosol	Hydrocarbon Solvent	Neville Chemical Co., Pittsburgh, Pa.
Covernishblak	Carbon Black Dispersions	Columbian Carbon Co., New York, New York
Coverlac	Solvent type strip coat	Spraylat Corp., New York, New York
Covinylblack	Carbon Black Dispersions	Columbian Carbon Co., New York, New York
Cratex	Abrasive Polishing Wheels, Points, Sticks, etc.	Cratex Mfg. Co., San Francisco 5, Calif.
Crealine	Plastic Pipe	Crescent Plastics, Inc., Evansville 7, Indiana
Crest-Foam	Vinyl foam	Crest Chemical Industries Corp., Brooklyn, N.Y.
Cryptone	Zinc sulphide pigments	The New Jersey Zinc Co., New York, New York
Crystal Seal	Clear molded styrene or acrylic with back decorated for third dimensional effect.	Gits Molding Corp., Chicago, Ill.
Crystolon	Abrasive, grinding wheels, refractories	Norton Co., Worcester, Mass.
Cub-line	Flexographic Printing Press	Wolverine Paper Converting Machinery Corp., Detroit, Michigan
Cub-Printer	Flexographic Printing Press	Wolverine Paper Converting Machinery Corp., Detroit, Michigan

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Curry Arts Laminations	Acrylic Decorative sheets, acetate and vinyl laminations, plexiglas fabrications	Curry Arts Laminating Co., Scranton, Pa.
Cush-N-Bio	Hand tool line	New Plastic Corp., Los Angeles, Calif.
Cycolac	Thermoplastic molding cmpds.	Marbon Chemical Div., Borg-Warner Corp., Gary, Indiana
Cymel	Melamine molding compounds and resins	Plastics & Resins Div., American Cyanamid Co., New York, N.Y.
	D	
DPR	Natural Depolymerized Rubber	H. V. Hardman Co., Inc., Belleville, New Jersey
Dacron	Polyester Fiber	E. I. du Pont de Nemour & Co., Inc., Wilmington, Delaware
Dake	Presses	Dake Corp., Grand Haven, Mich.
Dapon	Thermosetting resin	Ohio-Apex Div., Food Machinery & Chemical Corp., Nitro, West Virginia
Darex	Plasticizer, Polyvinyl Acetate Emulsion, High Styrene Copolymer Latex, High Styrene Copolymer Resin.	Dewey and Almy Chemical Co., Div. of W. R. Grace & Co., Cambridge, Mass.
Davis-Standard	Thermoplastic and rubber extruding machine and accessories	Davis-Standard, Div. of Franklin Research Corp., Mystic, Conn.
Daxad	Dispersing agent, either sodium or potassium salts of alkyl naphthalene sulfonic acid also by differing numbers, they are polymerized sodium salts of substituted benzoid alkyl sulfonic acid.	Dewey and Almy Chemical Co., Cambridge, Mass.
Day	Pony mixers, Dispersion or Roll Mills, Blenders, Imperial Dispersion Mixers, Sifters, Heavy Duty Double Arm Mixers.	J. H. Day Co., Cincinnati, Ohio
Daycor	Corrugated and Flat Sheet for non-structural uses.	Strick Plastics, Perkasie, Pennsylvania.
Decalin	Solvent	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Decor-Vac	Decorative Vacuum Formed Plastics.	W. L. Stenagaard and Associates, Inc., Chicago, Illinois
Densite	Gypsym cement—high strength	Beatwall Certain-Teed Sales Corp., Ardmore, Pennsylvania
Derbylite	Daylight—fluorescent molding powders and products	Luminous Resins, Inc., Chicago, Ill.
Devcon	80% Steel-20% Plastic for making Molds.	Chemical Development Corp., Danvers, Mass.
Dexstar	Long fibre specialty papers	C. H. Dexter & Sons, Inc., Windsor Locks, Conn.
Diall	Diallyl phthalate molding compounds	Mena Plastics Co., Los Angelea, California
Diamond	Vulcanized Fibre Sheets, rods, tubes	Continental-Diamond Fibre Corp., Newark, Delaware
Diatol	Denatured alcohol solvent	U. S. Industrial Chemicals Co., Div. of National Distillers and Chemical Corp., New York, New York
Dilecto	Laminated Plastic sheets, rods, tubes	Continental-Diamond Fibre Corp., Newark, Delaware
Dimetcote	Protective coating	Amercoat Corp., South Gate, California
Dispersions	Plastics Dispersion	Badische Anilin- & Soda Fabrik A. G., Germany
Diorid	Polyvinylidene chloride for production of filaments	Badische Anilin- & Soda Fabrik A. G., Germany
Dipentek	Dipentaerythritol technical	Heyden Chem. Corp., New York, N.Y.
Disperbite	Aqueous dispersions of rubber	Naugatuck Chemical, Div. of the U.S. Rubber Co., Naugatuck, Conn.
Donwood	Electrical and plastic	Sierra Electric Corp., Gardena, Calif.
Dorey	Metalized Mylar laminates	The Dorrie Process Co., Inc., Brooklyn, New York
Dorr	Vinyl film and sheeting and coated fabrics	Gordon-Lacy Chemical Products Co., Inc., Maspeth, L.I., N.Y.
Dow Corning	Silicone products	Dow Corning Corp., Midland, Mich.
Dropex	Plasticizers for Vinyl Resins	Argus Chemical Laboratory, Brooklyn, N.Y.
Drycal	Pigments for coloring Plastics	Gering Products, Inc., Kenilworth, N. Jersey
Dryply	Pre-impregnated polyester glass cloth and mat	Flexfirm Products, El Monte, Calif.
Duco	Enamels, Finishes, Lacquer Sealers	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Du Lite	Enamels	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Dulux	Foam Resin, Paints, Varnishes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Duol	Resinated chemical pigments	E. I. du Pont de Nemours & Co., Inc., Pigment Div., Wilmington, Del.
Duponol	Sodium Lauryl Sulfate, Surface Active Agents	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Duralon	Furane Resins	U. S. Stoneware Co., Akron, Ohio
Duratex	Supported vinyl fabric for automotive seatcovers and automotive trim.	Textileather Division, The General Tire & Rubber Co., Toledo, Ohio
Durex	Pipe and Fittings	Franklin Plastics, Inc., Franklin, Pennsylvania
Durez	Diallyl phthalate molding compounds, Phenolic resins, Phenolic molding compounds, Polyester molding compounds, Polyester resins (fire-retardant).	Durez Plastics Div., Hooker Electrochemical Co., North Tonawanda, New York
Dyal	Alkyd and Styrenated Alkyd Resins for Coatings	Sherwin-Williams Company, Pigment, Color and Chem. Div., New York, N.Y.
Dyfoam	Foam plastic insulation	Dyfoam Corp., New Castle, Pennsylvania
Dylan	Polyethylene	Koppers Company, Inc., Chemical Division, Pittsburgh, Pa.
Dylene	Polystyrene	Koppers Company, Inc., Chemical Division, Pittsburgh, Pa.
Dylite	Expandable polystyrene	Koppers Company, Inc., Chemical Division, Pittsburgh, Pa.
Dymal	Maleic Resins for Coatings	The Sherwin-Williams Co., New York, New York
Dynatherm	Electronic (dielectric) heating and sealing presses, ovens, and all related work handling equipment.	Guild Electronics Inc., New York, New York
Dyphene	Phenol-Formaldehyde Pure Resins for Coatings	Sherwin-Williams Co., Pigment, Color and Chem. Div., New York, N.Y.
Dyphenite	Phenol-formaldehyde, Modified Resins for Coatings	Sherwin-Williams Co., Pigment, Color and Chem. Div., New York, N.Y.
Dytron	Laminated Fabric	Dynamit-Actien-Gesellschaft, Troisdorf, W. Germany
	E	
Eccofoam	Foam products	Emerson and Cuming, Inc., Canton, Mass.
Eccosorb	Series of electromagnetic energy absorbers	Emerson & Cuming, Inc., Canton, Mass.
Elastofoam	Series of patented vinyl plastisol compounds	Elastomer Chemical Corp., Newark, N.J.
Elastolex	Elastic fabric supported vinyl	Texileather Division, The General Tire & Rubber Co., Toledo, Ohio
Electromax	Temperature Signalling Controller	Leeds & Northrup Co., Philadelphia, Pennsylvania
Electronheat	Dielectric Preheating Generators	Rendel Engineering Corp., Pasadena, Calif.
Elf	Channel Carbon Blacks	Godfrey L. Cabot, Inc., Boston, Massachusetts
Elftex	Oil Furnace Carbon Blacks	Godfrey L. Cabot, Inc., Boston, Massachusetts
Elmer's	Adhesives	The Borden Co., Chemical Div., New York, New York
Elmes	Hydraulic presses and equipment	Elmes Engineering Div., American Steel Foundries, Cincinnati, Ohio
Elprine	Rubber-Base coating	Atlas Mineral Products Co., Mertztown, Pennsylvania
Elvacet	Polyvinyl Acetate Emulsion	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Elvanol	Polyvinyl Alcohol	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Emerox	Azlaic Acid	Emery Industries, Inc., Cincinnati, Ohio
Emersol	Stearic and oleic acids	Emery Industries, Inc., Cincinnati, Ohio
Empol	Polymerized Acids	Emery Industries, Inc., Cincinnati, Ohio
Emulphor	Surfactant; emulsifying agent; latex stabilizer; antistatic agent.	Antara Chemicals, Div. of General Aniline & Film Corp. New York, New York
Emu-Pulver 120 FD	Styrene-containing mixed polymers, re-emulsifiable in water, for the production of aqueous dispersions for paints.	Badische Anilin- & Soda Fabrik A. G., Germany
Endura	Impregnated and coated papers	Endura Corp., Quakertown, Pennsylvania
Ensolex	Cellular plastic material in sheet form or extruded shapes for the construction industry.	United States Rubber Co., New York, New York.
Ensolite	Cellular plastic material in sheet form and extruded shapes	United States Rubber Co., New York, New York
Entoleter	Impact Mill and/or Centrifugal Mixer	Entoleter Div., Safety Industries, Inc., New Haven, Conn.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Epco	Drum tumblers and masterbatch (predispersed pigment in polyethylene)	Erie Plastics Co., Div. of Erie Iron & Supply Corp., Erie, Pa.
Epibond	Synthetic resins for use in adhesives	Furane Plastics, Inc., Los Angeles, Calif.
Epikote	Epoxy Resin	Shell Chemical Corp., New York, New York
Epi-Rez	Epoxy Resins	Jones-Dabney Co., Louisville, Ky.
Epi-Tex	Epoxy Ester Resins	Jones-Dabney Co., Louisville, Ky.
Epi-Ver	Epoxy Ester Resins	Jones-Dabney Co., Louisville, Ky.
Epocast	Casting, bonding and laminating resins	Furane Plastics, Inc., Los Angeles 39, Calif.
Epon	Epoxy resin for coatings, potting, laminating, adhesives and tool and die fabrication.	Shell Chemical Corp., New York, New York.
Epon Curing Agent	Hardeners for epoxy resin systems	Shell Chemical Corp., New York, New York
Eponite	Epoxy resin for textile treating	Shell Chemical Corp., New York, New York
Epoxylite	Epoxy resin formulations	The Epoxylite Corp., El Monte, Calif.
Erdco	RF generators for plastic sealing and presses.	Erdco Engineering Corp., Addison, Illinois.
Ethocel	Ethylcellulose	Dow Chemical Co., Midland, Mich.
Ethylac	Vulcanizing Agt.	Pennsylvania Salt Manufacturing Co., Industrial Div., Philadelphia, Pennsylvania
Everflex	Vinyl Acetate Copolymer Emulsion	Dewey and Almy Chemical Co., Div. of W. R. Grace & Co., Cambridge, Mass.
Exact Weight	Scales, Industrial and Commercial	Exact Weight Scale Co., Columbus, Ohio
Excelsior	Carbon Black	Columbian Carbon Co., New York, New York
Extrudolite	Embossed extruded sheets—Styrene, acrylics, etc.	Rotuba Extruders, Inc., Brooklyn, N.Y.
	F	
FA	Furfuryl Alcohol	The Quaker Oats Co., Chemicals Dept., Chicago, Illinois
Fabricfil	Chopped fabrics for filler in plastics.	The Rayon Processing Co. of Rhode Island, Pawtucket, R. I.
Fabrez	Urea-Formaldehyde Textile Resins	Reichhold Chemicals, Inc., White Plains, New York
Fabrikoid	Pyroxylin Coated Fabrics	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Fabrilite	Vinyl coated fabrics	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Fade-Ometer	Testing Apparatus, Accelerated Fading.	Atlas Electric Devices Co., Chicago, Illinois.
Fairprene	Synthetic Rubber Coated Fabrics	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Fairylite	Plastic Cellulose Derivative in Class 1 raw or partly prepared materials.	Shoe Form Co., Inc., Auburn, New York
Farlite	Decorative & Industrial High-pressure Laminated Plastics	Plastics Div., Farley & Loetscher Mfg. Co., Dubuque, Iowa
Farrel	Mills and Calenders	Farrel-Birmingham Co., Inc., Ansonia, Conn.
Farrel-Birmingham	Mills and Calenders	Farrel-Birmingham Co., Inc., Ansonia, Conn.
Fedaron	Polyvinyl chloride coated fabric	Federal Industries, Div. of Textron, Inc., Belleville, New Jersey
Feather Brand	Balsa cores for reinforced plastics.	International Balsa Corp., Jersey City, N.J.
Fedlastic	Polyvinyl chloride coated jersey	Federal Industries, Div. of Textron, Inc., Belleville, New Jersey
Fedroid	Pyroxylin coated fabric	Federal Industries, Div. of Textron, Inc., Belleville, New Jersey
Fedrolon	Polyvinyl chloride coated fabric	Federal Industries, Div. of Textron, Inc., Belleville, New Jersey
Fedwall	Polyvinyl chloride coated fabrics	Federal Industries, Div. Textron, Inc., Belleville, New Jersey
Ferrotron	Magnetic plastic materials	The Polymer Corp., Reading Pennsylvania
Fibercast	Reinforced Epoxy Pipe, Tubing and Fittings	The Fibercast Corp., Sand Springs, Oklahoma
Fibercore	Glass fiber reinforced molding compounds	Plumb Chemical Corp., Philadelphia, Pennsylvania
Fiberesin	Laminated Decorative Board and panel stock	Fiberesin Plastics Co., Oconomowoc, Wisconsin
Fiberite	Reinforced phenolic and Melamine Molding Materials	The Fiberite Corp., Winona, Minn.
Fiberthin	Coated Textile Fabric	United States Rubber Co., New York, New York
Fibrex	Fiber glass and Premix molding compound and molded parts.	General Plastics Corp. and General Fiber, Inc., Div. of General Plastics Corp., Los Angeles, Calif.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Filfloc	Random cut fibre for filler in plastics.	The Rayon Processing Co. of R. I., Pawtucket, R. I.
Filon	Translucent Fiberglass Reinforced Plastic Building Panel	Filon Plastics Corp., El Segundo, Calif.
Firco	Plastic treatment for fire hose . . . to prevent mildew & prolong life of hose.	General Plastics Mfg. Co., Tacoma, Wash.
Fire-Snuf	Flame Retardant Polyester Translucent Structural Panels.	Resolite Corp., Zelienople, Pennsylvania
Firestone Butaprene	Composition of synthetic rubber or rubber-like materials with or without natural rubber.	Firestone Plastics Co., Pottstown, Pa.
Firestone Exon	Raw or partly prepared plastic resins in the form of powders, granules, pellets, plastisols, or lattices for further use in the industrial arts.	Firestone Plastics Co., Pottstown, Pennsylvania
Firestone Valon	Vinyl film, sheeting, monofilaments and multifilament yarns	Firestone Plastics Co., Pottstown, Pennsylvania.
Flawmaster	A thermosetting compound used to reclaim metal parts and castings, otherwise rejected for surface flaws.	Carl H. Biggs Co., Inc., Los Angeles, Calif.
Flexaust	Flexible hose for dust collections, etc.	The Flexaust Co., New York, New York
Flexbond	Polyvinyl Acetate Emulsion	Colton Chemical Co., Div. Air Reduction Co., Inc., Cleveland, Ohio
Flex-I-Base	Bases of rubber and fabric for rubber cushions	United States Rubber Co., New York, New York
Flexol	Plasticizers	Carbide and Carbon Chemicals Co., New York, New York
Flex-O-Timer	Time-cycle controller	Taylor Instrument Companies, Rochester, New York
Flexrite Colors	Lacquer Colors	Flexcraft Industries, Newark, New Jersey
Flex Span	Liquid plastic-coating	Flexcraft Industries, Newark, New Jersey
Flextherm	Hot or cold therapeutic bandage.	Skyline Industries; Skyline Plastic Pipe, Inc; Skyline Plastic Molding, Inc., Titusville, Pennsylvania
Flo-Line	Pipe made of intermediate density Polyethylene.	Skyline Industries, Skyline Plastic Pipe, Inc., Skyline Plastic Molding, inc., Titusville, Pennsylvania
Florence	Zinc oxides	The New Jersey Zinc Co., New York, New York
Fluid-Feed	Rotary table & drill press feed.	Mead Specialties Co., Inc., Chicago, Illinois
Fluoroflex	Products made from Fluorocarbon Resins	Resistoflex Corp., Roseland, New Jersey
Fluoumseal	Pipe thread compound for plastic and steel joints, resistant to chemical attack and joints can be easily disassembled.	Industrial Plastic Fabricators, Inc., Norwood, Mass.
Fluran	Fluocarbon Products	U. S. Stoneware Co., Akron, Ohio
Forasite	Phenol-Formaldehyde Particle Board Adhesives	Reichhold Chemicals, Inc., White Plains, New York
Formacurve	Formed decorative laminated plastic materials.	Pine-Wood Plastic Co., Inc., Cambridge, Mass.
Formvar	Polyvinyl formal resins	Shawinigan Resins Corp., Springfield, Mass.
Fortical	Cellulosic Plastic	Plastics Div., Celanese Corp. of America, Newark, New Jersey
Fortiflex	Polyolefin Resin	Plastics Div., Celanese Corp. of America, Newark, New Jersey
Fostarene	Polystyrene	Foster Grant Co., Inc., Leominster, Mass.
Foundrez	Urea-Formaldehyde and Phenol-Formaldehyde Foundry Resins	Reichhold Chemicals, Corp., White Plains, New York
Franklin	Hard Vulcanized Fibre	Franklin Fibre-Lamitex Corp., Wilmington, Delaware
Fray-No	Fray proofing	Farrington Texol Corp., Walpole, Mass.
Fray-No-Therm	Heat sealable coating	Farrington Texol Corp., Walpole, Mass.
Fulscope	Indicating or Recording Controllers for temperature and pressure.	Taylor Instrument Companies, Rochester, New York
Fuse Film	Film and film laminate	Velveray Corp., New York, New York
Fyberoid	Very high grade insulating paper commonly called "Fish Paper."	Wilmington Fibre Specialty Co., New Castle, Dela.
	G	
G-K	Pipe joint compound	Atlas Mineral Products Co., Mertztown, Pennsylvania
Gelo	Casein	George Morrell Corp., Muskegon Heights, Mich.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Golorn	Casein	George Morrell Corp., Muskegon Heights, Mich.
Gomaco	Natural calcium carbonate extender water ground from White Georgia Crystalline.	The Calcium Products Div., The Georgia Marble Co., Tate, Georgia
Goralease	Mold release Laeguers	Garan Chemical Corp., Gardena, Calif.
Goralyst	Catalyst compositions	Garan Chemical Corp., Gardena, Calif.
Goran Goranized Goran Finish Garden Beauty	Glass fiber roving " " " " " " Extruded rigid vinyl garden fencing, stakes and trellises.	L. O. F. Glass Fibers Co., Toledo, Ohio Gering Products, Inc., Kenilworth, New Jersey
Gorox	Peroxide Compositions.	Garan Chemical Corp., Gardena, Calif.
Gel-Kote	Coating for polyester products. (molded with product).	The Glidden Co., Cleveland, Ohio
Gelva	Polyvinyl acetate resins	Shawinigan Resins Corp., Springfield, Mass.
Gelvatex	Aqueous polyvinyl acetate emulsions and paint bases and paints compounded therefrom.	Shawinigan Resins Corp., Springfield, Mass.
Gelvatol	Polyvinyl alcohol resins	Shawinigan Resins Corp., Springfield, Mass.
Gemacite	Molding of a thermosetting plastic for decorative articles.	Greene Plastics Corp., Hope Valley, R. I.
Gemwood	Laminated sheets consisting of pregwoods combined with plastic sheets, acrylic, phenolic, acetate, etc.	Gemwood Corp., Jamaica, N.Y.
Gen-Flo	Styrene Butadiene Latex	Chemical Div., General Tire & Rubber Co., Akron, Ohio
Genofil-Rohre	Unplasticized rigid-Tubing for pipes and structural uses in all colors.	Anorgana G.M.B.H. Munchen, Ger.
Genotex	Yarn for weaving of fine plastic textiles.	Anorgana G.M.B.H. Munchen, Germany
Genotherm	Unplasticized vinyl film-sheet-plate, from .0006" to .020" in rools-calendered-non toxic.	Anorgana G.M.B.H. Munchen, Germany
Gen-Tac	Rubber-to-fabric Vinyl Pyridine Adhesive Dip	Chemical Div., General Tire & Rubber Co., Akron, Ohio
Genton	Dispersions of Synthetic Resins.	General Dispersions, Inc., Paterson, New Jersey
Geon	Polyvinyl Chloride resins, compounds, and latices.	B. F. Goodrich Chemical Co., Cleveland, Ohio
Gen-Flex	Vinyl tubing	Gering Products, Inc., Kenilworth, New Jersey
Gerlite	Acrylic sheeting	Gering Products, Inc., Kenilworth, New Jersey
Gen-Pak	Polyethylene film	Gering Products, Inc., Kenilworth, New Jersey
Gen-Tube	Polyethylene tubing	Gering Products, Inc., Kenilworth, New Jersey
Gilco	Polystyrene Sheets, Polyethylene-roll and sheets	The Gilman Bros. Co., Gillman, Conn.
Glas-Bond	Adhesives	Polymer Industries, Inc., Springdale, Conn.
Glaskyd	Alkyd molding compounds	Glaskyd Inc., Perryaburg, Ohio
Glastic	Fiberglass reinforced plastics-flat sheets laminates, premix custom moldings, extruded rod stock, stator slot wedges.	The Glastic Corp., Cleveland, Ohio
Glasticote	A non-flammable liquid for cleaning, polishing and protecting plastic and glass surfaces. A light buffing compound for use on plastics. A mild release liquid for plastics.	Industrial and Domestic Silicone Distributor, Reseda, California
Glidpol	Basic material for molding, laminating, etc., of reinforced plastic products.	The Glidden Co., Cleveland, Ohio
Glitex	Plastic tubing for electrical insulation.	Genesee Laboratory, Inc., Auburn, New York
Globalite	Fluorescent Molding Powders and Products	Luminous Resins, Inc., Chicago, Illinois
Globlak	Carbon Black Dispersions	Columbian Carbon Co., New York, New York
Glykon	Polyester Resin	Chemical Div., General Tire & Rubber Co., Akron, Ohio
Glyptal	Pigmented resin-base paints, varnishes, enamels, alkyd resins.	Chemical Materials Dept., General Electric Co., Pittsfield, Mass.
Goldcote	Gold colored vacuum metalized finish.	The Eyelet Specialty Co., Waterbury, Conn.
Golpanol	Protective coating for metal and anti-corrosive metal.	Badische Anilin- & Soda Fabrik A. G., Germany
Goodallite	Vinyl coated fabrics	Goodall-Sanford, Inc., Reading, Mass.
Good-Rite	Chemicals	B. F. Goodrich Chemical Co., Cleveland, Ohio
Goodstix	Self sticking printed transparent advertising signs and product labels.	Goodrich Products Corp., Englewood, New Jersey
Grandur	Decorative plastic laminated furniture products.	Pine-Wood Plastic Co., Inc., Cambridge, Mass.
Grex	Linear (high density) Polyethylene	W. R. Grace & Co., Polymer Chemicals Div., Clifton, New Jersey

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Grip Flex	Special Decorative Coatings	Keystone Refining Co., Inc., Philadelphia, Pennsylvania
Guard	Vinyl wall covering	Columbus Coated Fabrics Corp., Columbus, Ohio
Gummon	Bituminous-asbestos cold molding compound. (organic)	Garfield Manufacturing Co., Garfield, New Jersey
Gusco	Epoxy and Epoxy Phenolic Coatings	A. Gushmer, Inc., Stalpic Div., Woodbridge, New Jersey
Gusher	Centrifugal pumps, Molten metal pumps	The Ruthman Machinery Co., Cincinnati, Ohio
Gusher Coolant Pump	Vertical centrifugal pump	The Ruthman Machinery Co., Cincinnati, Ohio
Guttano-Glasklar	Glass-clear-film in varying hardnesses-calendered-polished.	Anorgana G.M.B.H. Munchen, Germany
Gymseal	Clear Phenolic Floor Finish	McCloskey Varnish Co., Philadelphia, Pennsylvania.

H

H Kohnstamm Atlas HK	Pigment colors for general manufacturing purposes, including plastics.	H. Kohnstamm & Co., Inc., New York, New York
Halowax	Chlorinated naphthalenes	Union Carbide and Carbon Corp.
Hanna	Valves, riveters	Hanna Engineering Works, Chicago, Ill.
Hanna Flo-Set	Speed control waves	Hanna Engineering Works, Chicago, Ill.
Harflex	Plasticizers (adipates, sebacates, phthalates, and specialties.)	Harchem Div., Wallace & Tiernan, Inc., Belleville, N.J.
Harmon	Colors	B. F. Goodrich Chemical Co., Cleveland, Ohio
Hasko.Struct	Polyester resin impregnated fiberglass bonded to expanded foam.	Haskelite Mfg. Corp., Grand Rapids, Mich.
Haveg	Filled phenolic resin for chemical process equipment. Filled furan resin for chemical process equipment	Haveg Industries, Inc., Wilmington, Delaware
Haysite	Reinforced polyester	Hays Mfg. Co., Erie, Pennsylvania
Hextrex	Clear and pigmented baking lacquer	Rexton Finishes, Inc., Irvington, New Jersey
Heirloom	Alkyd Protective Coating	McCloskey Varnish Co., Philadelphia, Pennsylvania
Heliogen	Blue and green copper-phthalocyanine pigments.	General Dyestuff Co., Sales Div. of General Aniline & Film Corp., New York, New York
Heliozone	Inhibitor	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Hemit	Cement-asbestos cold molding compound. (inorganic)	Garfield Mfg. Co., Garfield, New Jersey
Hercocel	Cellulose acetate molding powder, ethyl cellulose molding powder.	Hercules Powder Co., Inc., Wilmington, Delaware
Herculflex	Plasticizers	Hercules Powder Co., Inc., Wilmington, Delaware
Hercolyn	Hydrogenated methyl abietate	Hercules Powder Co., Inc., Wilmington, Delaware
Hercules	Interchanging type holder	The Acromark Co., Elizabeth, New Jersey
Heresyn	Butadiene-Acrylonitrile Synthetic Rubber	Heresite & Chemical Co., Manitowoc, Wis.
Heresite	Phenolic coatings	Heresite & Chemical Co., Manitowoc, Wis.
Hetron	Polyester resins (fire-retardant)	Hooker Electrochemical Co., Durez Plastics Div., North Tonawanda, New York
Hexcel	Structural honeycomb material	Hexcel Products, Inc., Oakland, Calif.
Hexcelite	Decorative paneling using Hexcel aluminum honeycomb and window glass.	Hexcel Products, Inc., Oakland, Calif.
Hi-fax	Linear polyethylene	Hercules Powder Co., Inc., Wilmington, Pennsylvania
Hi-Line	Pipe made of linear Polyethylene	Skyline Industries; Skyline Plastic Pipe, Inc., Skyline Plastic Molding, Inc., Titusville, Pennsylvania
Hobe	Honeycomb before expansion	Hexcel Products, Inc., Oakland, Calif.
Horse Head	Zinc pigments, titanium dioxide pigments	The New Jersey Zinc Co., New York, New York
Hyben	Plastic sheeting, textile coating	Associated Rubber and Plastic Corp., New York, New York
Hycar	Acrylonitrile, polyacrylic, butyl, and styrene rubbers and latices.	B. F. Goodrich Chemical Co., Cleveland, Ohio
Hycryl	Modified Ammonium Polyacrylate Solution	U B S Chemical Corp., Cambridge, Mass.
Hydrite	Extender and inert filler pigment	Georgia Kaolin Co., Elizabeth, New Jersey
Hydro-Finish	Liquid blast machine used for cleaning molds, dies, etc.	Pangborn Corp., Hagerstown, Md.
Hydro-Line	Flexographic Printing Press	Wolverine Paper Converting Machinery Corp., Detroit, Mich.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Hydro-Printer	Flexographic Printing Press	Wolverine Paper Converting Machine Corp., Detroit, Mich.
Hylene	Organic isocyanates	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Hypalon	Synthetic rubber	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Hypervac	High vacuum pumps	Central Scientific Co., Chicago, Ill.
Hysol	Epoxy Resin Compounds and Amine and Anhydride Hardeners	Houghton Laboratories, Inc., Olean, New York
Hyvac	High vacuum pumps	Central Scientific Co., Chicago, Ill.
	I	
Igepal	Surfactant; emulsifier; antistatic agent; wetting agent.	Antara Chemicals, Div. of General Aniline & Film Corp., New York, New York
Igepon	Surfactant; wetting agent	Antara Chemicals, Div. of General Aniline & Film Corp., New York, New York
Im-Plast	High impact chemical resistant thermosetting plastic material used for containers for electrical storage batteries, etc.	The Richardson Co., Melrose Park, Ill.
IMS	Tumblers, grinders and machinery items. IMS mold release: zinc stearate dry powder, silicone sprays.	Injection Molders Supply Co., Cleveland, Ohio
IN	Radiation gauges used in measuring the physical properties of materials. Control equipt.	Industrial Nucleonics Corp., Columbus, Ohio
Ind	Thermosetting & Thermoplastic molding materials	Industrial Molded Products Co., Inc., Palatine, Ill.
Indur	Phenolic Molding Material	Pitt-Consol Chemical Co., Newark, New Jersey
Insultruc	Fiberglas polyester laminate.	Cincinnati Development & Manufacturing Co., Cincinnati, Ohio
Insurok	Laminated plastic sheet, tubes, gears, blanks, washers, discs, special punched and molded parts.	The Richardson Co., Melrose Park, Ill.
Interplastics	Thermoplastic Molding Powders	Interplastics Corp., New York, New York
Iolyte	Reinforced Plastic Fabrications	Schori Process, Div. Forro-co Corp., N.Y., N.Y.
Isasol	Solvent Soluble Dyes	National Aniline Div., Chemical & Dye Corp., New York, New York
Iporka	Urea resin and foam	Badische Anilin- & Sofa Fabrik, A. G., Germany
Irvinil	Polyvinyl chloride resin	Great American Plastics Co., Fitchburg, Mass.
Isanol	Lacquer solvent	Badische Anilin- & Soda Fabrik A. G., Germany
Isolite	Polyester Resins	Schenectady Varnish Co., Inc., Schenectady, New York
Isomelt	Polyurethane Wire Enamel	Schenectady Varnish Co., Inc., Schenectady, New York
Isonel	Polyester Wire Enamel	Schenectady Varnish Co., Inc., Schenectady, New York
Isoplast	Depolymerized rubber	Rubber & Asbestos Corp., Bloomfield, New Jersey
Isotemp Ovens	Ovens	Fisher Scientific Co., Pittsburgh, Pennsylvania
Ivo	Bone black	Columbian Carbon Co., New York, New York
	J	
JC-60	Pipe Joint Compound	Atlas Mineral Products Co., Mertztown, Pennsylvania
Jarco 88	Prelubricated nylon compound	Jim Robbins Co., Royal Oak, Mich.
Javelle	Citronella odorant	Fritzsche Brothers, Inc., New York, New York
Jek-o-mer	Liquid alkyd resin and solutions thereof both for use as coating compositions and as vehicles in making paints and enamels—additive for making thixotropic paints.	Alkydor Laboratories, Inc., Cicero, Ill.
Jet-Kote	Furane Resin Coatings	Furane Plastics, Inc., Los Angeles, Calif.
Jodo	Plastic materials and synthetic resin	Joseph Davis Plastics Co., Arlington, New Jersey
Johnson's	Prepared wax in paste, liquid, powdered form.	S. C. Johnson & Son, Inc., Racine, Wis.
Johnson's Wax	Wax products used as mold release agents.	S. C. Johnson & Son, Inc., Racine, Wis.
Jumbo Plate	Electrical and Plastic	Sierra Electric Corp., Gardena, Calif.
	K	
Kadox	Zinc oxides	The New Jersey Zinc Co., New York, New York
Kalite	Precipitated Calcium Carbonate	Diamond Alkali Co., Cleveland, Ohio
Kapsol	Plasticizers-oleate plasticizer	Ohio-Apex, Div. F.M.C., Nitro, W. Va.
Kaurit-Leim	Condensation product based on urea-formaldehyde; used for strong adhesion; waterproof.	Badische Anilin- & Soda Fabrik A. G., Germany
Kel-F	Molding powder & molded products. Polymer oils, greases, & waxes.	The M. W. Kellogg Co., Jersey City, New Jersey
Kendent	Diamond indenter for hardness testers	The Torsion Balance Co., Clifton, New Jersey
Kenflex	Synthetic Resin	Kenrich Corp., Maspeth, New York
Kentrall	Rockwell Type Hardness tester for both regular and superficial tests.	The Torsion Balance Co., Clifton, New Jersey
Kentron	Micro hardness tester	The Torsion Balance Co., Clifton, New Jersey
Keratol	Pyroxylin coated bookbinding fabric.	The General Tire & Rubber Co., Textileather Div., Toledo, Ohio
Kessco	Fatty Acid Ester and Plasticizers	Kessler Chemical Co., Inc., Philadelphia, Pennsylvania
Kleercor	Simultaneous extrusion of polyethylene pipe with a clear interior core and a black extruded sheath.	Western Plastic Corp., Hastings, Nebraska.
King Designers	Plastic & Die Cast Mold Design Engineers Plastic Consultants.	King Designers, Detroit, Mich.
Kling-Seal	Thermoplastic coated sheet material	Milprint, Inc., Milwaukee, Wis.
Ko-Blend	Insoluble Sulfex-GR-s Master Batch	General Tire & Rubber Co., Chemical Div., Akron, Ohio
Kodapak	Transparent sheeting	Eastman Kodak Co., Rochester, New York
Kopal	Processed Congo Copals	Reichhold Chemicals, Inc., White Plains, New York
Korasin	Vinyl resin on a phenolic base for the rubber industry.	Badische Anilin- & Soda Fabrik A. G., Germany
Korex	Rubber-Base Coating	Atlas Mineral Products Co., Mertztown, Pennsylvania
Koroseal	Plastisol compounds for sewer tile industry and rack coating industry.	The B. F. Goodrich Industrial Products Co., Div. B. F. Goodrich Co., Akron, Ohio
Korosheal	Vinyl coated fabric, vinyl film and sheet, vinyl flexible extrusions, vinyl pipe, fittings, sheet, rod, and tubing.	B. F. Goodrich Industrial Products Co., Plastic Div., Marietta, Ohio
Ketol	Solvent solutions of synthetic resins for protective coatings on machinery and tank linings.	Naugatuck Chemical, Div. of United States Rubber Co., Naugatuck, Conn.
Kralac	Thermoplastic resins for molding and forming.	Naugatuck Chemical, Div. of United States Rubber Co., Naugatuck, Conn.
Kralastic	Molding and extrusions compounds	Naugatuck Chemical, Div. of United States Rubber Co., Naugatuck, Conn.
Krene	Vinyl chloride-acetate calendered film and sheeting. Vinyl cast film.	Union Carbide and Carbon Corp.
Kromoplast	Dry colorant for thermoplastics	American Molding Powder & Chemical Corp., Brooklyn, N.Y.
Kronisol	Dibutixyethyl phth. plasticizer.	Ohio-Apex, Div. F.M.C., Nitro, W. Va.
Kronitex	Tricrisyl phophliate plasticizer	Ohio-Apex, Div. F.M.C., Nitro, W. Va.
Krylon	Plastic coating	Krylon, Inc., Norristown, Pennsylvania
Kure-Blend	Tetramethyl Thiuramdisulfide-GR-s	General Tire & Rubber Co., Chemical Div., Akron, Ohio
Kunsthars	Unsapohifiable synthetic resin, based on ketones, for weatherfast oil, alkyd, and nitrocellulose lacquers. Alcohol-soluble resin for nitrocellulose. Alcohol-soluble synthetic resin for waterproof nitrocellulose wood lacquers and nitrocellulose acetate lacquers.	Badische Anilin- & Soda Fabrik A. G., Germany
Kyo-lite	Resin-Gearing Fibrous Articles	Keyes Fibres Co., Waterville, Maine
	L	
Labelon	Tape, pressure-sensitive labels.	Labelon Tape Co., Inc., Rochester, New York
Lacrinoid	Finishing and Polishing Materials	Lacrinoid Products, Ltd., Essex, England

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Ledcote Compounds	Thermoplastic compounds	L. A. Dreyfuss Co., South Plainfield, New Jersey
Lemin-Art	Decorative Laminates	Fabricon Products, Div. The Eagle-Pitcher Co., River Rouge, Mich.
Leminac	Polyester Resins	American Cyanamid Co., Plastics & Resins Div., New York, New York
Lemitex	Laminated bakelite	Franklin Fibre-Lamitex Corp., Wilmington, Delaware
Lercrylic	Acrylic plastic sheet.	Larc Products, Inc., Amsterdam, New York
Leromin	Hardener for epoxies	Badische Anilin- & Soda Fabrik A. G., Germany
Leropal	Modified...ester for rapidly drying oil, alkyd, alcohol lacquers, etc.	Badische Anilin- & Soda Fabrik A. G., Germany
Letekoll	Thickening agent for dispersions	Badische Anilin- & Soda Fabrik A. G., Germany
Letyl	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Layflat	Plastic tubing	Plax Corp., Hartford, Conn.
Lauxite	Melamine, urea, phenolic and resorcinal resin adhesives.	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Leefluor	Teflon rods, sheets, tubes and molded fabricated parts.	Walt Lee Chemical Corp., Bronx, New York
Lemac	Polyvinyl acetate	The Borden Co., Chemical Div., New York
Lemol	Polyvinyl alcohol	The Borden Co., Chemical Div., New York, New York
Leucogen	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Leucosol	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Lignocol	Anti-Skinning Agent	Heyden Newport Chemical Corp., New York, New York.
Lignofol	Compregnated Laminated wood	Dynamit-Actien-Gesellschaft, Troisdorf, W. Germany
Lilion	Transmission belts, filters, wicks, gaskets, wiping cloths, and electronic or heat sealings.	Pellon Corp., New York, New York
Lithosol	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Logo	Solutions of organic polymeric substances to be used for surface treatment for plastics.	Logo, Inc., Chicago, Ill.
Logofoil	Strippable protective coating and composition.	Logo, Inc., Chicago, Ill.
Logoquant	Chemical Preparations, protective coating compositions for use on plastic articles.	Logo, Inc., Chicago, Ill.
Logoset	Synthetic enamels and varnishes	Logo, Inc., Chicago, Ill.
Lorol	Normal cetyl alcohol	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware.
Lotol	Compounded latices	Naugatuck Chemical, Div. of United States Rubber Co., Naugatuck, Conn.
Loxite	Elastomeric Adhesives	Xylos Rubber Co., Div. of Firestone Tire & Rubber Co., Akron, Ohio
Lucktin	Rapidly evaporating surface coating for oil and alkyd lacquers.	Badische Anilin- & Soda Fabrik A. G., Germany
Lucidol	Benzoyl Peroxide	Wallace & Tiernan, Inc., Lucidol Div., Buffalo, New York.
Lucite	Acrylic Resin	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Lumarith	Cellulosic plastic	Celanese Corp. of America, Plastics Div., Newark, New Jersey
Luperco	Organic Peroxide Compounds	Wallace & Tiernan, Inc., Lucidol Div., Buffalo, New York
Lumigraphic	These cover a range of shades from red, orange, yellow, and green fluorescent pigments.	Imperial Paper and Color Corp., Pigment Color Div., Glens Falls, N.Y.
Luperox	Organic Peroxide Pastes	Wallace & Tiernan, Inc., Lucidol Div., Buffalo, New York
Lupersol	Organic Peroxide Solutions	Wallace & Tiernan, Inc., Lucidol Div., Buffalo, New York
Luphen	Hardenable phenolic resin for chemical resistant lacquers and acid resistant coatings.	Badische Anilin- & Soda Fabrik A. G., Germany
Lupolen	High-molecular polyethylene	Badische Anilin- & Soda Fabrik A. G., Germany
Lusano	Brilliant Blue B Dye	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Lustrelite	Patterned pearlized acrylic sheet	U. S. Plastic Products Corp., Metuchen, New Jersey
Lustretone	Heat resistant pearlized button stock	U. S. Plastic Products Corp., Metuchen, New Jersey
Lutofan	Synthetic dispersions and solutions for paper and web coating.	Badische Anilin- & Soda Fabrik A. G., Germany
Lutonal	Unsaponifiable soft resins based on vinyl ether for adhesives	Badische Anilin- & Soda Fabrik A. G., Germany
Luvicon	Heat-resistant thermoplastic, specially for electronic applications	Badische Anilin- & Soda Fabrik A. G., Germany
Luxol	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Lytron	Polyelectrolyte resins and resins for use as foundry sand binders.	Monsanto Chemical Co., Plastics Div., Springfield, Mass.

M

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
MC-1	Catalyst	Celanese Corp. of America, Plastics Div., Newark, New Jersey
M. D. A.	Methylene Disalicylic Acid	Heyden Newport Chemical Corp., New York, New York
MR	Liquid Resin	Celanese Corp. of America, Plastics Div., Newark, New Jersey
MX	Fibreglass reinforced plastic lamp and lighting parts.	Marplex Co., El Segundo, California
Magic-Vulc	Adhesives & Coatings	Magic Chemical Co., Brockton, Mass.
Man O'War Ultra Spar	Phenolic Spar Varnish	McCloskey Varnish Co., Philadelphia, Pennsylvania
Mapico	Synthetic Iron Oxide Pigments	Columbian Carbon Co., Mapico Color Unit, New York, New York
Maraset	Epoxy resins	The Marblette Corp., Long Island City, New York
Marblette	Phenolic resins	The Marblette Corp., Long Island City, New York
Marbon 8000	High Styrene Resins	Borg-Warner Corp., Marbon Chemical Div., Gary, Indiana
Marco	Liquid Synthetic Resin	Celanese Corp. of America, Plastics Div., Newark, New Jersey
Marcothix	Thixotropic Polymer	Celanese Corp. of America, Plastics Div., Newark, New Jersey
Markonic	Marking service specialist	The Acromark Co., Elizabeth, New Jersey
Marlex	Olefin Polymer	Phillips Chemical Co., Barlesville, Oklahoma.
Marmix	Resin Emulsions	Marbon Chemical Div., Borg-Warner Corp., Gary, Indiana
Marvibond	Laminated sheets of plastic on metal.	United States Rubber Co., Naugatuck Chemical Div., Naugatuck, Conn.
Marvinol	Vinyl resins and compounds	Naugatuck Chemical, Div. of United States Rubber Co., Naugatuck, Conn.
Master Color	Concentrated pigment dispersions (Master-Batch) for thermoplastics materials.	American Molding Powder & Chemical Corp., Brooklyn, N.Y.
Mead	Air devices, etc.	Mead Specialties Co., Inc., Chicago, Ill.
Meadmatic	Pneumatic Timers, valves	Mead Specialties Co., Inc., Chicago, Ill.
Mearlmaid	Natural Pearl Essence	Mearl Corp., New York, New York
Megavac	High Vacuum Pumps	Central Scientific Co., Chicago, Ill.
Melmac	Molded quality melamine dinnerware.	American Cyanamid Co., Plastics & Resins Div., New York, New York
Melurac	Resin adhesives, Melamine-Urea-Formal.	American Cyanamid Co., Plastics & Resins Div., New York, New York
Merac	Water soluble rubber Latex Accelerator	Pennsylvania Salt Mfg. Co., Industrial Div., Philadelphia, Pennsylvania
Mercadiums	Cadmium Mercury Oranges, Reds, and Maroons	Imperial Paper and Color Corp., Pigment Color Div., Glens Falls, New York
Merix Anti-Fog	Fog-Preventative Chemical for plastic and glass surface	Merix Chemical Co., Chicago, Ill.
Merix Anti-Static	De-Staticizing Chemical (plastics), Anti-Static for Fabrics & Plastic Seatcovers.	Merix Chemical Co., Chicago, Ill.
Merix TV Tele Clear	Television tubes and Lens. Destaticizer/Cleanser (plastic & glass)	Merix Chemical Co., Chicago, Ill.
Merpentine	Surface Active Agent	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware.
Merpol	Surface Active Agent	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Metaflex	Embossed Mylar Laminated to Vinyl Coated Products Including Fabric Base.	L. E. Carpenter & Co., Wharton, New Jersey
Methac	Methanol-methyl acetate solvent	The Borden Co., Chemical Div., New York, New York

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Methocel	Methylcellulose	Dow Chemical Co., Midland, Mich.
Methox	Dimethoxyettiyl phthalate plasticizer	Ohio-Apex, Div. F.M.C., Nitro, W. Va.
Methylon	Phenolic coating resin	General Electric Co., Chemical Materials Dept., Pittsfield, Mass.
Metso	Sodium metasilicate pentahydrate, Sodium metasilicate anhydrous, Sodium orthosilicate concentrated, Sodium sesquisilicate pentahydrate	Philadelphia Quartz Co., Phil., Pa.
Micabond	Bonded mica insulating material	Continental-Diamond Fibre Corp., Newark, Delaware
Michigan Fiber-Glas Sales	Fiber-Glas Materials, Resins & Supplies	Michigan Fiber-Glas Sales, East Detroit, Mich.
Micronex	Carbon black	Columbian Carbon Co., New York, New York
Micronizer	Jet Pulverizer	Sturtevant Mill Co., Boston, Mass.
Microsurfacer	Sizing machine for surfacing thin sheeting	Buss Machine Works, Holland, Mich.
Midlon	Film and sheets in cellulose acetate, cellulose acetate butyrate, modified polystyrene, polyethylene, acrylic.	Midwest Plastic Products Co., Chicago Heights, Ill.
Milfilm	Laminated packaging material	Milprint, Inc., Milwaukee, Wis.
Mil-O-Casing	Meat casings	Milprint, Inc., Milwaukee, Wis.
Mil-O-Film	Plastic sheets, bags, & wrappers	Milprint, Inc., Milwaukee, Wis.
Mil-O-Seal	Pliofilm & Cellphane meat casings	Milprint, Inc., Milwaukee, Wis.
Mini-Jector	Injection molding machines	Newbury Industries Inc., Newbury, Ohio
Mipelon	PVC Copolymers	Dynamit-Actien-Gesellschaft, Troisdorf, W. Germany
Miracle	Black magic adhesive, ceramic tile cements, tub caulk, plastic underlayment, dry wall adhesive, wallboard cement, industrial adhesives & coating, insulation adhesives.	Miracle Adhesives Corp., Bellmore, New York
Mirasol	Alkyd Resins	C. J. Osborn Co., Linden, New Jersey
Mirro-Brite	Metallized, Acetate, Butyrate Polystyrene & "Mylar"	Coating Products, Englewood, New Jersey
Mobeloy	Polyester reinforced Fibreglass	Cordo Chemical Corp., Norwalk, Conn.
Mobay	Organic chemicals including isocyanates, carbamyl halides; synthetic resins including polyesters; chemical intermediates for polyurethane plastics; catalysts and other additives for use in making polyurethan plastics; polyurethan plastics foam and homogeneous polyurethane plastics.	Mobay Chemical Co., St. Louis, Mo.
Modulatic	Steam generator	Vapor Heating Corp., Chicago, Ill.
Mogul	Channel carbon black	Godfrey L. Cabot, Inc., Boston, Mass.
Moldexe F. 47	Mold Release Compound	The Moldrite Products Company, Providence, R. I.
Molgard	Internal Mold Releases	Garan Chemical Corp., Gardena, Calif.
Monarch	Medium color channel carbon black	Godfrey L. Cabot, Inc., Boston, Mass.
Monarchrome	Range of Green shades from light to deep made by co-precipitating Phthalocyanine Blue and Chrome yellow.	Imperial Paper and Color Corp., Pigment Color Div., Glens Falls, New York
Mondur	Isocyanates and synthetic resins including polyesters.	Mobay Chemical Co., St. Louis, Mo.
Monite	Casein Adhesives	Monite Waterproof Glue Co., Minneapolis, Minn.
Monofast	Textile Pigments, Plastic Compounds	H. Kohnstamm & Co., Inc., New York, New York
Monopaan	Paints, varnishes, enamels, etc.	Interchemical Corp., Finishers Div., Newark, New Jersey
Monopentek	Monopentaerythritol	Heyden Newport Chemical Corp., New York, New York
Monterey	Plastic wall tile, heavy gauge	Skyline Industries; Skyline Plastic Pipe, Inc.; Skyline Plastic Molding, Inc., Titusville, Penna.
Morflex	Plasticizers	Morton-Withers Chemical Co., Greensboro, N.C.
Moto-steel	Diaphragm operated valve motors	Taylor Instrument Companies, Rochester, New York
Mr. N	Ammonium Nitrate Fertilizer	Spencer Chemical Co., Kansas City, Mo.
Multifoam	Readers	J. A. Richards Co., Kalamazoo, Mich.
Multifex MM	Precipitated Calcium Carbonate	Diamond Alkali Co., Cleveland, Ohio
Multimatic	Automatic Dispenser	Archer Label Co., Los Angeles, Calif.
Multiplastics	Fiberglass kits for industrial repairs and boat coverings.	Curd Enterprizes, Inc., Multiplastics Div., Addison, Ill.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Multipruf	Vinyl coated fabric	Elm Coated Fabrics Co., Inc., New York, N.Y.
Multitrip	Woven Wood and Wire Containers for industrial handling.	G. B. Lewis Co., Watertown, Wis.
Multranil	Synthetic resins and catalysts for use in making polyrethane plastics.	Mobay Chemical Co., St. Louis, Mo.
Multron	Synthetic resins including polyesters.	Mobay Chemical Co., St. Louis, Mo.
Mustang	Composition supported vinyl	General Tire & Rubber Co., Textileather Div., Toledo, Ohio
Mycalex	Glass-bonded mica	Mycalex Corp. of America, Clifton, New Jersey
Myleroy	Glass bonded mica	Electronic Mechanics, Inc., Clifton, New Jersey

N

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
NP	For sheaves, quills, bobbins, twisters, and idlers.	National Plastics, Inc., Knoxville, Tennessee
NR Pliolite	Cyclized rubber coating resins	The Goodyear Tire and Rubber Co., Akron, Ohio
Naccanol	Detergent	Allied Chemical & Dye Corp., National Aniline Div., New York, New York
Naccosol	Wetting agent	Allied Chemical & Dye Corp., National Aniline Div., New York, New York
Naccotan	Dispersing Agent	Allied Chemical & Dye Corp., National Aniline Div., New York, New York
Nacrinor	Synthetic Pearl Pigments	Mearl Corp., New York, New York.
Nadic	Anhydride for Alkyds & Polyesters	National Aniline Div., Allied Chemical & Dye Corp., New York, New York
Naphthanil	Diazo Colors	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Nash	Air Compressors, Vacuum pumps	The Nash Engineering Co., South Norwalk, Conn.
Naugatex	Butadiene-Styrene latices	Naugatuck Chemicals, Div. of United States Rubber Co., Naugatuck, Conn.
Naugahyde	Vinyl coated fabric	United States Rubber Co., New York, New York
Naugalite	Coated Fabric	U. S. Rubber Co., New York, N.Y.
Naugalon	Fabrics coated with Waterproofing Material	U. S. Rubber Co., New York, N.Y.
Naugatop	Carriage cloth (fabric & rubber)	U. S. Rubber Co., New York, N.Y.
Nebony	Petroleum Hydrocarbon Resin	Neville Chemical Co., Pittsburgh 25, Pa.
Neelium	High solids neoprene coating	The Atlas Mineral Products Co., Mertztown, Pa.
Nekal	Wetting agent	Antara Chemicals, Sales Div. General Aniline & Film Corp., New York, New York
Neo-Spectra	Carbon Black	Columbian Carbon Co., New York, New York
Neoben	Neoprene high build coating	The Atlas Mineral Products Co., Mertztown, Penna.
Neomorpin	Surface Active Agent	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Neozone	Rubber Antioxidants	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware.
Nepoxide	Modified epoxyresin coating	The Atlas Mineral Products Co., Mertztown, Penna.
Neutroleum	Odor modifier for rubber, vinyl, and plasticizers.	Fritzsche Bros., Inc., New York, New York
Neutroscent	Perfume for surface dressing of finished plastics	Fritzsche Bros., Inc., New York, New York
Nevamar	High-pressure decorative laminates	The National Plastic Products Co., Odenton, Md.
Nevillac	Phenol-Modified Coumarone-Indene Resin	Neville Chemical Co., Pittsburgh 25, Pa.
Neville LX-685	Petroleum Hydrocarbon Resin	Neville Chemical Co., Pittsburgh 25, Pa.
Neville LX-702	Petroleum Hydrocarbon Resin	Neville Chemical Co., Pittsburgh 25, Pa.
Nevindene	Coumarone-Indene Resin	Neville Chemical Co., Neville Island, Pittsburgh 25, Pa.
Nevinol	Plasticizing Oil	Neville Chemical Co., Pittsburgh 25, Pa.
Nevsolv	Hydrocarbon Solvent	Neville Chemical Co., Pittsburgh 25, Pa.
Niacet	Vinyl Acetate	Carbide and Carbon Chemicals Co., New York, New York
Nibroc	Base stock for high pressure laminates	Brown Co., Boston, Mass.
Nicoform	Electroformed molds for plastics	Electromold Corp., Trenton, New Jersey
Nitration Cellulose	For cellulose nitrate lacquers and explosives	Rayonier, Inc., New York, New York
Nitrex	Synthetic rubber latex	Naugatuck Chemical Div., U.S. Rubber Co., Naugatuck, Conn.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Nitrex	Synthetic Rubber lattices	Naugatuck Chemical, Div. United States Rubber Co., Naugatuck, Conn.
Nitrocol	Nitrocellulose Base Pigment Dispersion	C. J. Osborn Co., Linden, New Jersey
Non-Fer-Al	Precipitated Calcium Carbonate	Diamond Alkali Co., Cleveland, Ohio
Non-Flam	Plastic Cellulose Derivative, a raw material in sheet form in class 1 raw or partly prepared materials.	Shoe Form Co., Inc., Auburn, New York
Nonic	Non-ionic wetting agent	Pennsylvania Salt Mfg. Co., Industiral Div., Philadelphia, Penna.
Norloc	Handles	Norton Laboratories, Inc., Lockport, New York
Norplex	Laminated Plastics	Northern Plastics Corp., La Crosse, Wis.
Novabestos	Asbestos and/or glass papers and mats for plastic reinforcement and electrical insulation.	Raybestos-Manhattan, Inc., Manheim, Pa.
Nuba	Modified Coumarone-Indene Resin	Neville Chemical Co., Pittsburgh 25, Pa.
Nuplo	All-Products-Hand Tools-Tile, etc.	New Plastic Corp., Los Angeles, Calif.
Nuplaflex	Raw material	New Plastic Corp., Los Angeles, Calif.
Nuplamold	Hand tool line	New Plastic Corp., Los Angeles, Calif.
Nusoil	General mixing varnish	McCloskey Varnish Co., Philadelphia, Penna.
Nylastint	Finely divided nylon molding powders	The Polymer Corp., Reading, Penna.
Nylatint	Nylon dyes	The Polymer Corp., Reading, Penna.
Nylatron	Filled nylons	The Polymer Corp., Reading, Penna.
Nylaweld	Nylon to nylon adhesives	The Polymer Corp., Reading, Penna.
Nyvel	Nylon and film laminate	Velveray Corp., New York, N.Y.
Nylaflow	Nylon pressure tubing	The Polymer Corp., Reading, Penna.

O

Ocenol	Oleyl Alcohol	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Ohmaid	Laminated phenolic plastic equivalent to bakelite, micarta, etc.	Wilmington Fibre Specialty Co., New Castle, Dela-
Ohapex	Specialty plasticizers	Ohio-Apex, Div. F.M.C., Nitro, W. Va.
Oilgear	Fluid Power Equipment	The Oilgear Co., Milwaukee, Wis.
Omya	Calcium carbonate (chalk whiting)	Pluess-Staufer (North American) Inc., New York, New York
Olin	Cellophane, Polyethylene	Olin Mathieson Chemical Corp., Film Division, New York, New York
Opalon	Vinyl chloride molding resin.	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Oppanol	Polyisobutylene of various degrees of viscosity	Badische Anilin- & Soda Fabrik A. G., Germany
Orlan	Acrylic Fiber	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Oronite	Solvent, preming solution, thinner, cresylic acids, phenol, phthalic anhydride-ie. (oronite cresylic acid; oronite phenol; oronite phthalic anhydride)	Oronite Chemical Co., San Francisco, Calif.
Oxidex	Anti-oxidant for animal and vegetable fats and oils.	Fritzsche Bros., Inc., New York, New York
Oxy Cold Bar	Static eliminators	Herbert Products, Inc., Woodhaven, New York

P

P. H. I.	Hydraulic presses w/heated platen of steam or electric of tonnage capacities ranging from 20 to 125 ton and platen sizes 8"×8" to 241/2" ×241/2" on our standard line. Also custom designing of presses.	Pasadena Hydraulics, Inc., El Monte, Calif.
PI	Textile Spools	Engineered Plastics, Inc., Gibsonville, North Carolina
PPC	Custom molding	Penn-Plastics Corp., Glenside, Penna.
PT 600	Medium pine tar	Godfrey L. Cabot, Inc., Boston, Mass.
Paladin	Primers for non-ferrous metals and plastics.	Interchemical Corp., Finishes Div., Newark, New Jersey
Palatal	Polyester resins for lacquers and casting	Badische Anilin- & Soda Fabrik A. G., Germany
Palatinol	Softeners for lacquers, plastics, and film-forming materials.	Badische Anilin- & Soda Fabrik A. G., Germany
Panaflex	Hydrocarbon plasticizer	Amoco Chemicals Corp., Chicago, Ill.
Panalon	Resin finish, Resin dispersion	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Panarez	Hydrocarbon resins.	Amoco Chemicals Corp., Chicago, Ill.
Pantasote	Vinyl coated fabric	The Pantasote Co., New York, N.Y.
Pantex	Unsupported vinyl film.	The Pantasote Co., New York, N.Y.
Parasril	Synthetic nitrite type rubber	Naugatuck Chemical, Div. United States Rubber Co., Naugatuck, Conn.
Parasepts	Esters of para-Hydroxy benzoic acid, preservatives.	Heyden Newport Chemical Corp., New York, New York
Paratex	Chlorinated Rubber Paints	Truscon Laboratories, Div. Devoe and Reynolds Co., Inc., Detroit, Mich.
Parcloid	Vinyl resin dispersions	Parcloid Chemical Corp., Midland Park, New Jersey
Paulite	Phosphorescent molding powders and products.	Luminous Resins, Inc., Chicago, Ill.
Pee Vee Cee	Polyvinylchloride sheet	Atlas Mineral Products Co., Mertztown, Pa.
Pellon	Non-woven inner construction material as a lining, interfacing, interlining, or backing for shape renetion purposes.	Pellon Corp., New York, New York
Pent-Acetate	Synthetic Amyl Acetate	Pennsylvania Salt Mfg. Co., Industrial Div., Phila., Penna.
Pentacite	Pentaerythritol Resins.	Reichhold Chemicals, Inc., White Plains, New York
Pentalene 95	Plasticizer extender	Pennsylvania Salt Mfg. Co., Industrial Div., Philadelphia, Penna.
Pentaphen	Para-Tert-Amylphenol	Pennsylvania Salt Mfg. Co., Industrial Div., Phila., Penna.
Pentasol	Synthetic Amyl Alcohol	Pennsylvania Salt Mfg. Co., Industrial Div., Phila., Penna.
Pentek	Pentaerythritol technical	Heyden Newport Chemical Corp., New York, New York
Penton	Linear polyethylene	Hercules Powder Co., Inc., Wilmington, Dela.
Permalux	Neoprene Accelerator	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Permaplast	Chemical resistant molded rubber compositions used for electric storage battery containers.	The Richardson Co., Melrose Park, Ill.
Perma-Skin	Vinyl and epoxy coatings	Dennis Chemical Co., St. Louis, Mo.
Permelite	Reinforced melamine molding compounds	Melamine Plastics, Inc., Winona, Minn.
Permolith	Lithopane	The Sherwin-Williams Co., New York, New York
Petrothene	Polyethylene resin	U. S. Industrial Chemicals Co., Div. National Distillers and Chemical Corp., New York, New York
Phtalopal	Alcohol soluble phthalic resins for nitrocellulose wood lacquers.	Badische Anilin- & Soda Fabrik A. G., Germany
Phenopreg	Phenolic, melamine, polyester, silicone, and epoxy resin impregnated paper, fabric, glass cloth and mat.	Fabricon Products, Div. The Eagle-Pitcher Co., River Rouge, Mich.
Phenoweld	Industrial Adhesive	H. V. Hardman Co., Inc., Belleville, New Jersey
Picco	Coal tar solvents, coating solutions, rubber softener, etc.	Pennsylvania Industrial Chemical Corp., Clairton, Penna.
Piccocizer	Plasticizer	Pennsylvania Industrial Chemical Corp., Clairton, Penna.
Piccolastic	Styrene Polymers	Pennsylvania Industrial Chemical Corp., Clairton, Penna.
Piccolyte	Terpene resins	Pennsylvania Industrial Chemical Corp., Clairton, Penna.
Piccoumaron	Hydrocarbon resins	Pennsylvania Industrial Chemical Corp., Clairton, Penna.
Piccopale	Petroleum resins	Pennsylvania Industrial Chemical Corp., Clairton, Penna.
Pinto	Composition supported vinyl	The General Tire & Rubber Co., Textileather Div., Toledo, Ohio
Pittsburgh PX	Plasticizers & Epoxy Plasticizers	Pittsburgh Coke & Chemical Co., Pittsburgh, Pa.
Placco	Flat acrylic paint	Customs Coatings Co., Los Angeles, Calif.
Plastilock	Adhesive-structural bonding Agents	The B. F. Goodrich Industrial Products Co., Div. B. F. Goodrich Co., Akron, Ohio
Plastiken	Adhesive-general purpose and cements and putties.	The B. F. Goodrich Industrial Products Co., Div. B. F. Goodrich, Co., Akron, Ohio

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Piccover	Hydrocarbon resins	Pennsylvania Industrial Chemical Corp., Clairton, Penna.
Piacquer	Semi-gloss acrylic paint	Custom Coatings Co., Los Angeles, Calif.
Piaspreg	Furane resin impreg. compound.	Furane Plastics, Inc., Los Angeles, Calif.
Plastacele	Cellulose acetate plastic	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Plasticone	Colorants (red)	The Sherwin-Williams Co., New York, New York
Plastigen	Soft resins for lacquers, based on nitrocellulose and other fil formers.	Badische Anilin- & Soda Fabrik A. G., Germany
Plastisand	Phenolic resin coated sand	Acme Resin Corp., Forest Park, Ill.
Plastolein	Plasticizers for vinyls, celluloses and synthetic rubbers.	Emery Industries, Inc., Cincinnati, Ohio
Plastolyn	Vinyl coated fabric	Columbus Coated Fabrics Corp., Columbus, Ohio
Plastomoll	Softeners for lacquers and plastics	Badische Anilin- & Soda Fabrik A. G., Germany
Plastopal	Urea formaldehyde for lacquers, acid-resistant coating, and nitrocellulose lacquers.	Badische Anilin- & Soda Fabrik A. G., Germany
Plastro	Dye for Plastics & Lacquer	Allied Chemical & Dye Corp., National Aniline Div., New York, New York
Plastrong	Re-enforced polyester premixed molding compound.	George Morrell Corp., Muskegon Heights, Mich.
Plo-Tank	Reinforced Polyester for chemical process equipt.	Haveg Industries, Inc., Wilmington. Dela.
Plonco	Phenolic Molding Compounds and Resins.	Plastics Engineering Co., Sheboygan, Wisc.
Pliobond	Rubber base adhesives	The Goodyear Tire and Rubber Co., Akron, Ohio
Pliogrip	"	
Pliotac	"	
Pliolite	Styrene/butadiene rubber reinforcing resins. Styrene butadiene coating resins.	The Goodyear Tire and Rubber Co., Akron, Ohio
Pliolite Latices	Styrene/butadiene copolymer latices	The Coodyear Tire and Rubber Co., Akron, Ohio
Plio-Tuf	Styrene copolymer high impact resins	The Goodyear Tire and Rubber Co., Akron, Ohio
Pliovic	Vinyl chloride polymer and copolymer resins.	The Goodyear Tire and Rubber Co., Akron, Ohio
Pleogen	Polyester resin	American Petrochemical Corp., Mol-Rez Div., Minneapolis, Minn.
Plyacton	Protein adhesives	Reichhold Chemicals, Inc., White Plains, New York
Plyamine	Urea-formaldehyde resins, adhesives, and varnishes.	Reichhold Chemicals, Inc., White Plains, New York
Plyamul	Polyvinyl acetate adhesives	Reichhold Chemicals, Inc., White Plains, New York
Plyophn	Phenol-formaldehyde resins, adhesives and varnishes.	Reichhold Chemicals, Inc., White Plains, New York
Polectron	Vinyl carbazole molding compound; resin polymer	Antara Chemicals, Div. General Aniline & Film Corp., New York, New York
Polesthan	Water-white, polyester embedments	Hanley Plastics Co., St. Louis, Mo.
Pollopas	Carbamide Resin	Dynamit-Actien-Gesellschaft, Troisdorf, Germany
Polyamin P	For waterproof artificial leather and for improving water resistance of paper.	Badische Anilin- & Soda Fabrik A. G., Germany
Polybond	Adhesive and textile finishing and weaving compounds	Polymer Industries, Inc., Springdale, Conn.
Poly-Box Carboy	Polyethylene Carbon in patented wood jacket.	Industrial Plastic Supply, Div. Isaco, Inc., West Hartford, Conn.
Polycast	Cast sheet	The Polycast Corp., Stanford, Conn.
Polyco	Resin emulsions	The Borden Co., Chemical Div., New York, New York
Poly-Eth	Polyethylene Resins	Spencer Chemical Co., Kansas City, Mo.
Polyfilm	Polyethylene film	Extruders, Inc., Hawthorne, Calif.
Polyflex	Film and sheet of plastic composition including oriented polystyrene	Plax Corp., Hartford, Conn.
Poly-Flo	Plastic (pvc) Polyvinyl-Chloride fabrication of precision parts.	Electro-Chemical Products Corp., Cleveland, Ohio
Polyfluoron	Polychlorofluoro Ethylene	Acme Resin Corp., Forest Park, Ill.
Polygard	Stabilizer for use in rubber and plastics.	Naugatuck Chemical, Div. United States Rubber Co., Naugatuck, Conn.
Polygum	Textile printing compounds	Polymer Industries, Inc., Springdale, Conn.
Polyken	Polyethylene film (linear concational), Polyethylene electrical tape, Polyethylene protective tape coatings	The Kendall Co., Polyken Sales Div., Chicago, Ill.
Poly-Kleen	Liquid cleanser	Schwartz Chemical Co., Inc., New York, New York
Poly-Lite	Side and bottom panels for fluorescent lighting fixtures.	Sandee Mfg. Co., Chicago, Ill.
Polylite	Polyester resins	Polyester resins, Reichhold Chemicals, Inc.
Polymerin	Melamine-Alkyd enamel	Interchemical Corp., Finishes Div., Newark, New Jersey
Polymix	Dry blended colored polyethylene	Gering Products, Inc., Kenilworth, New Jersey
Polypenco	Nylon and Teflon molded products.	The Polymer Corp., Reading, Penna.
Polyprene	Vinyl Organosol Enamel	Interchemical Corp., Finishes Div., Newark, New Jersey
Polyrez	Industrial Synthetic resins in the form of Liquids, Solutions, Emulsions, Powders, and Lump.	Polyrez Co., Inc., Woodbury, N.J.
Polytex	Multicolored specks in one application by spraying	Atlas Coatings Corp., Long Island City, New York
Polytreat	Polyethylene film (treated for printing)	Extruders, Inc., Hawthorne, Calif.
Ponsol	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Pontachrome	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Pontacyl	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Delaware
Pontamine	Dyes, Diazo Dyes, Fast Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Por-C-Lyn	Baked enamel finishes of exceptional hardness.	Atlas Coatings Corp., Long Island City, New York
Polytherm	Silicone enamels	Interchemical Corp., Finishes Div., Newark, New Jersey
Pre-Imp	Pre-impregnated chopped rovings	Flexfirm Products, El Monte, Calif.
Pressure-Line	Flexible Polyethylene Pipe with built-in steel, wire mesh, tape or fabric reinforcement	Skyline Industries; Skyline Plastic Pipe, Inc.; Skyline Plastic Molding, Inc., Titusville, Penna.
Propiofan	Plastics dispersion based on acrylic ester	Badische Anilin- & Soda Fabrik A. G., Germany
Protecto-Flex	"Zip-on" vinyl pipe insulation cover.	Miracle Adhesives Corp., Bellmore, New York
Protektinsul	"Zip-on" vinyl pipe insulation cover.	Miracles Adhesives Corp., Bellmore, New York
Protox	Zinc oxides	The New Jersey Zinc Co., New York, New York
Prox-melt	Modified paraffin waxes.	Pyroxylin Products, Inc., Chicago, Ill.
Prox-peel	Strippable coatings	Pyroxylin Products, Inc., Chicago, Ill.
Pyralin	Cellulose Nitrate Plastic	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Pyrocon	Contact pyrometer for surface and other temperature measurement.	Illinois Testing Laboratories, Inc., Chicago, Ill.

Q

QO	Furan Chemicals and Derivatives	The Quaker Oats Co., Chemicals Dept., Chicago, Ill.
Quakerol	Furfural	The Quaker Oats Co., Chemicals Dept., Chicago, Ill.
Quinorgo	Electrical insulations of purified asbestos with organic binder. For use as is or for further treatment.	Johns-Manville, New York, New York
Quinorgobord	Highly purified asbestos base sheet materials for fabrication into electrical insulations.	Johns-Manville, New York, New York
Quinterro	Electrical insulations of 100% purified asbestos base sheet, resin-treated; also same as laminates reinforced with glass cloth or plastic film.	Johns-Manville, New York, New York
Quso	Finely divided amorphous silica.	Philadelphia Quartz Co., Phila., Penna.

R

RC	Natural and synthetic rubber compounds. Plasticizers, plastisols, rigidsols	Rubber Corp. of America, New York, N. Y.
R-Mix-Dek	Non-slip coating floor and deck coating.	Miracle Adhesives Corp., Bellmore, New York
Rx	Sheets of phenolic resin forming paperboard.	Consolidated Paper Co., Monroe, Mich.
Radialloy-tipped	Carbide tipped tools	Radial Cutter Manufacturing Corp., Elizabeth, New Jersey
Remapo	Pigments	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Randoc	Thermosetting resins for impregnating, encapsulating, etc. of electrical and electronic components.	Mitchell Rand Mfg. Corp., New York, New York
Raven	Carbon black	Columbian Carbon Co., New York, New York
Rayacete	For cellulose acetate	Rayonier Inc., New York, New York

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Raybrite	For plastics reinforcement	Rayonier Inc., New York, New York
Raymix	Random cut rayon flock for surface coating.	The Rayon Processing Co. of R. I., Pawtucket, R. I.
Raytallics	Metallic particle for decorative filler in plastics.	The Rayon Processing Co. of R. I., Pawtucket, R. I.
Realite	Decorative high pressure melamine laminates	Reina Associates, Inc., Lowell, Mass.
Reet	Vinyl and polyethylene film and sheeting.	Ross & Roberts Co., Stratford, Conn.
Reevon	Polyethylene filaments and fabrics.	Reeves Brothers, Inc., New York, New York
Refrasil	Silica Fiber Textiles and Batting	H. I. Thompson Fiber Glass Co., Los Angeles
Resimine	Melamine resins, liquid and solid	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Resinite Vinyl Insulation Sleeving	Insulation sleeving and tubing	The Borden Co., Resinite Dept., Santa Barbara, Calif.
Resinite	Thermoplastic synthetic resin wire & cable insulation sleeving	The Borden Co., Chemical Div., New York, New York
Resinox	Phenolic molding resin	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Resloom	Textile finishing resins	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Resmetal	Metallic patching paste, self-hardening solder.	The Borden Co., Chemical Div., New York, New York
Resoform	Colorants	General Dyestuff Co., Div. General Aniline & Film Corp., New York, New York
Resorsabond	Resorcinol Resins	American-Marietta Co., Adhesive, Resin & Chemical Div., Seattle, Wash.
Resproid	Vinyl film sheeting and coated fabric.	The General Tire and Rubber Co., Respro Div., Cranston, Ohio
Reswax	Synthetic wax-resin combination	The Borden Co., Chemical Div., New York, New York
Rexatherm	Baking enamels	Texton Finishes, Inc., Irvington, New Jersey
Rexlacq	Air dry lacquers	Rexton Finishes, Inc., Irvington, New Jersey
Rez-N-Bond	Cement for acrylics and styrene	Schwartz Chemical Co., Inc., New York, New York
Rez-N-Dye	Cold Dip Liquid Dyes	Schwartz Chemical Co., Inc., New York, New York
Rez-N-Glue	All purpose adhesive	Schwartz Chemical Co., Inc., New York, New York
Rez-N-Kleen	Liquid cleaner	Schwartz Chemical Co., Inc., New York, New York
Rez-N-Lac	Lacquers for all plastics.	Schwartz Chemical Co., Inc., New York, New York
Rez-N-Polish	Powder cleaner & anti static	Schwartz Chemical Co., Inc., New York, New York
Richelain	Decorative laminated sheets used for table tops and panels. Furniture drawers molded from plastic materials.	The Richardson Co., Melrose Park, Ill.
Rigidcast	Cast Thermosetting	Heil Process Equipt. Corp., Rigidon Plastic Div., Cleveland, Ohio
Rigidene	Fabricated Polyethylene	Heil Process Equipt. Corp., Rigidon Plastic Div., Cleveland, Ohio
Rigidon	Glass reinforced Polyester	Heil Process Equipt. Corp., Rigidon Plastic Div., Cleveland, Ohio
Rigivin	Rigid vinyl sheet fabrication	Heil Process Equipt. Corp., Rigidon Plastic Div., Cleveland, Ohio
Rincontrol	Wrinkle enamels	Interchemical Corp., Finishes Div., Newark, New Jersey
Rippolite	Structural glass panels made from glass fiber reinforced plastic material.	Rippolite Plastic Products, Inc., Burbank, Calif.
RO-Ball	Gyrating screen sifters	J. H. Day Co., Cincinnati, Ohio
Release	Rubber roll covering for Polyethylene Laminating.	Stowe-Woodward, Inc., Newton Upper Falls, Mass.
Rolox	Adhesives for paint rollers	H. V. Hardman Co., Inc., Belleville, New Jersey
Roracyl	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Rotalin	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Roxoprene	Chlorinated Rubber Enamel	Interchemical Corp., Finishes Div., Newark, New Jersey
Royal Master	Centerless grinding machine	Royal Master, Inc., Riverdale, New Jersey
Rub-Erok	Molded hard rubber x-ray development tanks, tank frames, and tank covers.	The Richardson Co., Melrose Park, Ill.
Rucoam	Vinyl film and sheeting	Rubber Corp. of America, Hicksville, New York
Ruddflex	Elastameric embossed sheeting & film printed, pressed polished and laminated, Poly-vinyl chloride, Poly-vinyl Butyral, Vinyl Formal, Rigid sheeting, Silicones and Elastomeric, Fluocarbons, Fancy Laminates, Styrene Copolymers, Vinyl coated cloth.	Rudd Plastic Fabrics Corp., Brooklyn, New York
Rumaco	Electrical motor driven and belt driven horizontal pumps with or without tanks.	The Ruthman Machinery Co., Cincinnati, Ohio
Ryertex-Omicron PVC	Polyvinylchloride Plastic	Joseph T. Ryerson & Son, Inc., Chicago, Ill.

S

Saflex	Plastic interliner for safety glass.	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Safrella	Sassafras odorant	Fritzsche Bros., Inc., New York, New York
Saf-T-Dek	Alkyd Base-Troweled on	Truscon Laboratories, Div. Devoe and Raynolds Co., Inc., Detroit, Mich.
San-D-Lite	Polyethylene sheet materials	Sandee Mfg. Co., Chicago, Ill.
Sandt	Die presses, mechanical and hydraulic. Embossing machines. Perforating machines. Other type equipment.	Atlas-Sandt Corp., New York, New York
Sanitized	Bacteriostat	The Sanitized Sales Co. of America, Inc., New York, New York
Sarcotrol	Mold temperature controller	Sarco Co., Inc., New York, New York
Scriptite	Synthetic resins for use as pigment binding agents.	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Sealerine	Concrete sealer	Customs Coatings Co., Los Angeles, Calif.
Sealdbin	Flexible, durable, collapsible container, of multi-ply rubber-coated cord fabric—for shipping of corrosive liquids and dry flowable solids	United States Rubber Co., New York, New York
Sealdtank	Flexible, durable, collapsible container, of multi-ply rubber-coated cord fabric—for shipping and storage of corrosive liquids.	United States Rubber Co., New York, New York
Sealz	Rubberized bitumens	Naugatuck Chemical Div., U. S. Rubber Co., Naugatuck, Conn.
Sea-Deep	Decorative plastics	Hoosier Cardinal Corp., Cardinal Div., Evansville, Indiana
Seilon	P. V. C., Styrene & Polyethylene rolls & sheets for vacuum forming	Seiberling Rubber Co., Plastics Div., Newcomerstown, Ohio
Sevron	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Shaperoll	Collar Stay	Ormond Mfg. Co., Inc., Union City, New Jersey
Shellblast	Soft grit blasting material made of nut shells and used for blast cleaning of molds.	Agrashell, Inc., Los Angeles, Calif.
Sierracin	Cast transparent polyester sheet and monolithic and laminated	The Sierracin Corp., Burbank, Calif.
Sierracote	Transparent conductive coating for heating plastic or glass surfaces.	The Sierracin Corp., Burbank, Calif.
Silastic	Silicone Rubber	Dow Corning Corp., Midland, Mich.
Silcobest	Laminated glass cloth slot wedges	Silicone Insulation, Inc., Bronx, New York
Silvacel	Extender filler and additive (fiber)	Weyerhaeuser Timber Co., Special Prods. Div., Tacoma, Wash.
Silvacon	Extender, filler, and additive (bark)	Weyerhaeuser Timber Co., Special Prods. Div., Tacoma, Wash.
Silvacote	Silver colored vacuum metalized finish.	The Eyelet Specialty Co., Waterbury, Conn.
Silvatrim	Plastic trim	Glass Laboratories, Inc., Brooklyn, New York
Silvaley	Moldable wood fiber	Weyerhaeuser Timber Co., Special Prods. Div., Tacoma, Wash.
Silverlite	Polished, anodized, heavy, sanitary type aluminum. Edging have a silver finish.	Pine-Wood Plastic Co., Inc., Cambridge, Mass.
Sirco Nut Shell Flour	Nut shell flour used as fillers—coconut shell flour, walnut shell flour, pecan shell flour, apricot pit flour, etc.	Bernard Sirotta Co., Brooklyn 31, N. Y.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Sircoblast	Ground Nut Shell Pellets for soft-grit blast-cleaning of metals, molds, and for deflashing of molded plastic products (ground walnut shells, coconut shell, pecan shells, apricot pits, etc.)	Bernard Sirotta Co., Brooklyn, New York
Solfast	Colorants (red and blue)	The Sherwin-Williams Co., New York, New York
Solka-Floc	Finely-divided purified cellulose.	Brown Co., Boston, Mass.
Solox	Denatured Alcohol Solvent	U. S. Industrial Chemicals Co., Div. National Distillers and Chemical Corp., New York, New York
Solozone	Sodium Peroxide	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Solvenon	Dimethyl acetate for solvents and thinner for lackers	Badische Anilin- & Soda Fabrik A. G., Germany
Solvic	Vinyl chloride polymers and vinyl chloride vinyl acetate copolymers	S. A. Solvic, Brussels, Belgium
Spac	Anti-static agent	S. M. Edison Chemical Co., Chicago, Ill.
Span	Emulsifying Agent	Atlas Powder Co., Wilmington, Dela.
Sphinx	Adhesives	Arabol Mfg. Co., New York, New York
Special Acetate Cellulose	For cellulose acetate	Rayonier, Inc., New York, New York
Speedrex	Epoxy resin paints	Truscon Laboratories, Div. Devoe and Raynolds Co., Inc., Detroit, Mich.
Spectro-Chrome	Metallic insert extrusion.	Schwab Plastics Corp., Detroit, Mich.
Span-Amm	Anhydrous Ammonia	Spencer Chemical Co., Kansas City, Mo.
Spansol	Nitrogen solutions	Spencer Chemical Co., Kansas City, Mo.
Spired	Extruding machine with electric heating and high velocity evaporative cooling.	John Royle & Sons, Paterson, N. J.
Spiroyl	Extruding machine with circulating heating and cooling.	John Royle & Sons, Paterson, N. J.
Spraylat	Water base strippable protective coating compounds	Spraylat Corp., New York, New York
Stack-n-Nest	Reinforced polyester tote pan designed to stack and nest within its own dimensions without mechanical aid.	G. B. Lewis Co., Watertown, Wis.
Stalpic	Phenol formaldehyde resin coatings.	A. Gusmer, Inc., Stalpic Div., Woodbridge, New Jersey
Statex	Carbon black	Columbian Carbon Co., New York, New York
Stearite	Hydrogenated stearic acid	Witco Chemical Co., New York, New York
Stixso	Silicate adhesive	Philadelphia Quartz Co., Phila., Penna.
Stenetex	Exterior masonry oil base paint	Truscon Laboratories, Div. Devoe and Raynolds Co., Inc., Detroit, Mich.
S-T-R-E-T-C-H	Polyethylene color concentrate	Gering Products, Inc., Kenilworth, New Jersey
Strip-a-Tube	Multiple Tubes (vinyl)	Jessall Plastics, Inc., Kensington, Conn.
Stycast	A series of casting resins—polyesters, epoxides, etc.	Emerson & Cuming, Inc., Canton, Mass.
Stylplast	Urea-formaldehyde molding compounds	American Viscose Corp., Phila., Penna.
Stymer	Synthetic resins for general use (textiles)	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Styresol	Styrenated Alkyd Resins	Reichhold Chemicals, Inc., White Plains, New York
Stypol	Polyester resin	H. H. Robertson Co., Pittsburgh, Penna.
Styratex	Styrenated Alkyd Resins	Jones-Dabney Co., Louisville, Ky.
Styrex	Copolymer Styrene Acrylonitrile.	Dow Chemical Co., Midland, Mich.
Styrofan	Plastics dispersions for impregnating and coatings.	Badische Anilin- & Soda Fabrik A. G., Germany
Styropor	Foamable polystyrene for the production of porous bodies of any shape	Badische Anilin- & Soda Fabrik A. G., Germany
Styrofoam	Expanded Polystyrene	Dow Chemical Co., Midland, Mich.
Styromix	Dry blended color pre-mixed styrene	Gering Products, Inc., Kenilworth, New Jersey
Styron	Molding Materials	Dow Chemical Co., Midland, Mich.
Sulfanthrene	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Sulfogene	Dyes	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Sullvac	Thermoplastic sheeting rigid and semi-rigid vacuum formable.	O'Sullivan Rubber Corp., Winchester, Va.
Sullvyne	Unsupported vinyl plastic sheeting	O'Sullivan Rubber Corp., Winchester, Va.
Sullvyne-Clad	Unsupported vinyl plastic sheeting laminated to various metals: steel, aluminum, magnesium.	O'Sullivan Rubber Corp., Winchester, Va.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Sunform	Flexible sheet material made of glass fibres impregnated with a thermosetting resin base composition, for use in the fabrication of rigid multiple ply laminated structures.	Electro-Technical Products, Div. San Chemical Corp., Nutley, New Jersey
Superblo	Carbon black	Columbian Carbon Co., New York, New York
Supercarbovar	Medium color channel carbon black	Godfrey L. Cabot, Inc., Boston, Mass.
Super Dylan	Polyethylene (low pressure)	Koppers Co., Inc., Chemical Div., Pittsburgh, Penna.
Superlith	Pure zinc sulphide & concentrated lithopone.	C. J. Osborn Co., Linden, N. J.
Super Multiflex	Precipitated Calcium Carbonate	Diamond Alkali Co., Cleveland, Ohio
Supertone	Urea Formaldehyde Moulding Powder	Lacrinoid Products, Ltd., Essex, England
Surfex	Precipitated Calcium Carbonate	Diamond Alkali Co., Cleveland, Ohio
Suspense	Precipitated Calcium Carbonate	Diamond Alkali Co., Cleveland, Ohio
Swirlustre	Hi-lustre pearlized patterned acrylic sheet	U. S. Plastic Products Corp., Metuchen, New Jersey
Synvaren	Liquid Phenolid Resins	Synvar Corp., Wilmington, Dela.
Sylkyd	Silicone Alkyd Resin	Dow Corning Corp., Midland, Mich.
Syncast	Synthetic resins for casting application	Synco Resins, Inc., Bethel, Conn.
Synco	Phenolic resins	Synco Resins, Inc., Bethel, Conn.
Syncoat	Synthetic resin coatings	Synco Resins, Inc., Bethel, Conn.
Synsize	Urea-formaldehyde resins—Liquid type	Synco Resins, Inc., Bethel, Conn.
Synthane	Laminated plastic products	Synthane Corp., Oaks, Penna.
Syntex	Alkyd Resins	Jones-Dabney Co., Louisville, Ky.
Syntho-Copal	Ester gums and ester gum solutions	Reichhold Chemicals, Inc., White Plains, New York
Syn-U-Tex	Urea-formaldehyde Resins	Jones-Dabney Co., Louisville, Ky.
Synvarite	Powdered urea and phenolic resins	Synvar Corp., Wilmington, Dela.
Synvarol	Liquid Urea Resins	Synvar Corp., Wilmington, Dela.
Supramica	Ceramoplastics	Mycalex Corp. of America, Clifton, New Jersey
Syracawood	Molded decorative accessories	Syracuse Ornamental Co., Inc., Syracuse, New York

T

THFA	Tetrahydrofurfuryl Alcohol	The Quaker Oats Co., Chemicals Dept., Chicago, Ill.
TME	Trimethylolethane	Heyden Chem. Corp., New York 17, N.Y.
TMP	Trimethylolpropane	Heyden Chem. Corp., New York 17, N.Y.
T. S. I.	Teflon rod	Tri-Point Plastics, Inc., Alberson, New York
Tackmaster	Pressure sensitive film adhesive	Rubber and Asbestos Corp., Bloomfield, New Jersey
Tap-Lok (Insert)	Internally & externally threaded bushing	Groov-Pin Corporation, Ridgefield, N. Jersey
Technoscent	Heat resistant plastic odorant	Fritzsche Bros., Inc., New York, New York
Teflon	Tetrafluoroethylene resin & coated glass fabrics, dispersion and molding compounds	E. I. du Pont de Nemours & Co., Inc., Polychemicals Dept., Wilmington 98, Dela.
Tegit	Phenolic-asbestos compound	Garfield Manufacturing Co., Garfield, N.J.
Tenite Acetate	Cellulose acetate-molding composition	Eastman Chemical Products, Inc., Kingsport, Tennessee
Tenite Butyrate	Cellulose acetate butyrate-molding composition	Eastman Chemical Products, Inc., Kingsport, Tenn.
Tenite Polyethylene	Polyethylene molding composition	Eastman Chem. Products, Inc., Kingsport, Tenn.
Tensglex	Latex impregnated paper for labels and misc. printed items.	The Sorg Paper Co., Middletown, Ohio
Tensilite	Laminated Paper Base Plastic	The J. P. Lewis Co., Plastic Products Div., Beaver Falls, N.Y.
Tepidone	Rubber accelerator	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Terasol	30 Polyalkylene ether glycol	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Terek	Cellulose Coated Fabrics	Athol Mfg. Co., New York, New York
Terokon	Cellulose coated paper	Athol Mfg. Co., New York, New York
Teroson	Vinyl coated paper	Athol Mfg. Co., New York, New York
Terpitol	Surface-active agents	Carbide & Carbon Chemicals Co., New York 17, N.Y.
Terson	Vinyl coated fabrics	Athol Mfg. Co., New York, New York.

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Tetrolin	Solvent	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Tetrone	Rubber accelerator	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Texol	Plastic artificial leather	Farrington Texol Corp., Walpole, Mass.
Texolex	Plastic coated papers	Farrington Texol Corp., Walpole, Mass.
Textileather	Pyroxylin coated fabric	The General Tire & Rubber Co., Textileather Div., Toledo, Ohio
Textilube	Lubricant used for lubricating bronze bushings used in textile equipment.	National Plastics, Inc., Knoxville, Tenn.
Tex-Trude	Spray nozzles and plastic pipe and fittings.	Texas Plastic Products Co., Houston, Texas.
Thermaband	Cast electric band heaters	Thermel, Inc., Franklin Park, Ill.
Thermacartridge	Electric cartridge heaters	Thermel, Inc., Franklin Park, Ill.
Thermo-fin	Electrical heating of extruders	Davis-Standard Sales Corp., sole selling agts. for The Standard Machinery Co., Mystic, Connecticut
Thermoheater	Cast electric heaters	Thermel, Inc., Franklin Park, Ill.
Thermoplaten	Cast electric platen heaters.	Thermel, Inc., Franklin Park, Ill.
Thermatron	High frequency heat sealing and pre-heating equipment.	Radio Receptor Co., Inc., New York, New York
Thermex	High frequency preheating equipment	The Girdler Co.-Thermex Div., A Div. of National Cylinder Gas Co., Louisville 1, Kentucky
Thermotube	Tubular type electric heaters.	Thermel, Inc., Franklin Park, Ill.
Thermo-Chock	Pipe insulation expanded styrene	Schwab Plastics Corp., Detroit, Mich.
Thermoflex	Rubber antioxidants	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Thermomat	Woven heat panels for industrial puposess	Thermomat Co., Inc., Trenton, New Jersey
Thermoscent	Deodorant for plastics	Fritzsche Brothers, Inc., New York, 11, N.Y.
Thionox	Rubber accelerator	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Thor	Resin emulsions	The Borden Co., Chemical Div., New York, New York
Titanox	White colorants (pigments) for plastics-titanium dioxide as primary pigmenting substance	Titanium Pigment Corp., New York, New York
Toolplastik	Plastic materials for tooling	Rezolin, Inc., Santa Monica, Calif.
Tolex	Fabric supported vinyl	The General Tire and Rubber Co., Textileather Div., Toledo, Ohio
Tolon	Unsupported vinyl sheeting	The General Tire & Rubber Co., Textileather Div., Toledo, Ohio
TorBal	Subminiature toggle switch	The Torsion Balance Co., Clifton, New Jersey
Tourex	Extruded vinyl binding and welting.	Waljohn Plastics, Inc., Brooklyn, New York
Toxilic	Maleic acid and anhydride	National Aniline Div., Allied Chemical & Dye Corp., New York, New York
Transaire	Temperature and pressure transmitters	Taylor Instrument Co., Rochester, New York
Transphalt	Hydrocarbon Polymers	Pennsylvania Industrial Chemical Corp., Clairton, Penna.
Transvair	Pneumatic Conv. System	The Young Machinery Co., Muncy, Penna.
Treadmaster	Retread cement	Rubber and Asbestos Corp., Bloomfield, New Jersey
Trevarno	Phenolic, Polyester, Epoxy, Silicone resin impregnating glass cloth	Coast Mfg. & Supply Co., Livermore, Calif.
Tripentek	Tripentaerythritol technical	Heyden Chem. Corp., New York 17, N.Y.
Trinseal	Teflon sub-miniature terminals	Tri-point plastics, Inc., Albertson, New York
Tri-point	3-color mechanical pencil	Nichol's Product's Co., Moorestown, New Jersey
Trogamid	Polyamide bars	Dynamit-Actien-Gesellschaft, Troisdorf, W. Germany
Trolitan	Stone powder	Dynamit-Actien-Gesellschaft, Troisdorf, W. Germany
Trovidur	Hard PVC blocks, sheets, etc.	Dynamit-Actien-Gesellschaft, Troisdorf, W. Germany
Troytuf	Non-woven fiber reinforcing and surfacing mat.	Troy Blanket Mills, New York, New York
Tuft-Tite	Electronically quilted vinyl sheeting and film.	The Barr Corp., Richmond Hill, New York
Tulfex	Latex Impregnated Label Stock	Archer Label Co., Los Angeles, Calif.
Tungseal	Penetrating Phenolic Sealer	McCloskey Varnish Co., Philadelphia, Penna.
Turbo-Dryer	Dryer-continuous, Desolventizer, Sublimer, Gas reactor	Wyssmont Co., Inc., Long Island City, New York
Turon	Non-woven fabric supported vinyl	The General Tire & Rubber Co., Textileather Div., Toledo, Ohio

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Tween	Emulsifiers	Atlas Powder Co., Wilmington 99, Delaware
Tygobond-30	Adhesive	U. S. Stoneware Co., Akron, Ohio
Tygon	Vinyl-type tubing, paint, etc.	U. S. Stoneware Co., Akron, Ohio
Tygoweld	Adhesive	U. S. Stoneware Co., Akron, Ohio
Tylene	Tooling plastics	Tylene Plastics, Inc., Michigan City, Indiana
Tynex	Nylon bristles, Nylon filaments	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Ty Ply	Rubber &Metal Bonding Agents	Marbon Chem. Div. of Borg-Warner Corp., Gary, Ind.

U

U. S. I. Isosebacic	Mixture of Isomers of Sebacic Acid.	U. S. Industrial Chemicals Co., Div. National Distillers and Chemical Corp., New York, New York
Ubatol	Modified Polystyrene and Acrylic Emulsions.	U B S Chemical Corp., Cambridge, Mass.
Ultramid	Extremely hard, heat resistant plastics, with good surface hardness.	Badische Anilin- & Soda Fabrik A. G., Germany
Ultrapas	Melamine Resin	Dynamit-Actien-Gesellschaft, Troisdorf, W. Germany
Ultron	Vinyl chloride molding resin. Vinyl chloride film and sheets.	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Unicel	Blowing agent	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Unifab	Industrial reinforcing fabrics-made from fiber glass.	Ferro Corp., Fiber glass div., Nashville, Tenn.
Uniformat	Chopped strand reinforcing mat- made from fiber glass	Ferro Corp., Fiber Glass Div., Nashville, Tenn.
Union Carbide	Polyethylene, Vinyl, Phenolic and Polystyrene, Plastics Resins and Compounds.	Union Carbide International Co., Div. Union Carbide and Carbon Corp., Plastics Dept. New York, New York
Unirove	Woven roving- made from fiber glass.	Ferro Corp., Fiber glass div., Nashville, Tenn.
Unitite	Hand operated valves.	Hanna Engineering Works, Chicago, Ill.
Unitized	Conveyors	Long Island Equipment Corp., Long Island City, New York.
Unitool	Hydraulic Valves and presses.	Clifton Hydraulic Press Co., Clifton, New Jersey
Unitrol	Hydraulic press	Clifton Hydraulic Press Co., Clifton, New Jersey
Urac	Resin adhesives, urea-formaldehydes	American Cyanamid Co., Plastics & Resins Div., New York, New York
Urecall	Binder for wastewood board and articles molded of such.	Badische Anilin- & Soda Fabrik A. G., Germany
Urefoam	Isocyanate resin expanded foam.	Atlas Mineral Products Co., Mertztown, Penna.
Uvinul	Ultraviolet light absorber; light stabilizer	Antara Chemicals, Div. General Aniline & Film Corp., New York, New York

V

VC-2	Vinyl cement	Schwartz Chemical Co., Inc., New York, New York
Valite	Thermosetting Phenolic Resins derived from Bagasse. Phenolic molding compounds. Phenolic laminating resins. Shell molding resins Phenolic adhesives. Thermoplastic resins used as extenders for vinyl, styreme, ethyl, cellulose, etc.	Valite Corp., New Orleans, La.
Valveseal	Liquid level control storage battery covers.	The Richardson Co., Melrose Park, Ill.
Van-Cor	Plastic pipe and fittings	The Van Dorn Iron Works Co., Cleveland, Ohio
Varlac	An exceptionally high gloss varnish type finish in rapid drying.	Atlas Coatings Corp., L.I.C., New York
Velbac	Napped sheeting and vinyl laminate	Velveray Corp., New York, N.Y.
Velvetex	Film and sheeting laminate	Velveray Corp., New York, N.Y.
Vibrafoam	Cellular Urethane Sheet or Molded Goods.	United States Rubber Co., New York, New York
Vibrin	Polyester resins	Naugatuck Chemical, Div. United States Rubber Co., Naugatuck, Conn.
Vichrome	Vinyl enamels	Interchemical Corp., Finishes Div., Newark, New Jersey
Vicro-Lite	Vinyl coated products for fabrication of movie screens.	L. E. Carpenter & Co., Wharton, New Jersey
Vicrotex	Vinyl coated fabrics	L. E. Carpenter & Co., Wharton, New Jersey
Vinac	Polyvinyl Acetate Emulsion	Colton Chemical Co., Div. Air Reduction Co., Inc., Cleveland, Ohio

TRADE NAME	NATURE OR TYPE OF PRODUCT	COMPANY & ADDRESS
Vinaplas-Lac	Vinyl lacquer	Schwartz Chemical Co., Inc., New York, New York
Vinaquilt	Quilted plastic fabrics	Marbek, Inc., Brooklyn, New York
Vinaflex	Vinyl chloride mixed polymer for film formers used in chemical resistant paints.	Badische Anilin- & Soda Fabrik A. G., Germany
Vinol	Polyvinyl alcohol	Colton Chemical Co., Div. Air Reduction Co., Inc., Cleveland, Ohio
Vin-Se-Lite	Foam Vinyl-ether-open cell structures or unicellular structures.	Foam King, Inc., Bronx, New York
Vinylac	Organic tackifiers	The Borden Co., Chemical Div., New York, New York
Vinylite	Vinyl chloride-acetate coated paper and automobile rear window sheeting, vinyl butyral for auto safety glass.	Union Carbide and Carbon Corp., New York
Vinylite	Vinylite film, sheeting, and vinyl compounds produced by Canadian Resins and Chemicals Limited.	Canadian Resins and Chemicals Limited, Montreal, Quebec, Canada.
Vinylum	Aluminum Powder Dispersions	Argus Chemical Corp., Brooklyn, New York
Viplo	Polyvinyl Chloride Resin and copolymers.	Chemore Corp., New York, New York
Vitron	Glass fibre roving.	L. O. F. Glass Fibers Co., Toledo, Ohio
Vitroplast	Polyester cement	Atlas Mineral Products Co., Mertztown, Penna.
Voplex	Vinyl plastic hose and tube.	Vogt Mfg. Corp., Rochester, N.Y.
Vuepak	Cellulose acetate film	Monsanto Chemical Co., Plastics Div., Springfield, Mass.
Vulcalock	Adhesive-rubber to metals and general purpose adhesives.	The B. F. Goodrich Products Co., Div. B. F. Goodrich Co., Akron, Ohio
Vulcan	Oil furnace carbon black.	Godfrey L. Cabot, Inc., Boston, Mass.
Vulcoid	Resin impregnated vulcanized fibre.	Continental-Diamond Corp., Newark, New Jersey
Vygen	Poly (vinyl chloride) Resin	General Tire & Rubber Co., Chemical Div., Akron, Ohio

W

Wallfab	Reinforced plastic flat sheet.	M. C. Gill Corp., El Monte, Calif.
Wallkyd	Alkyd flat wall vehicles	Reichhold Chemicals, Inc., White Plains, New York
Wallpol	Polyvinyl acetate emulsions	Reichhold Chemicals, Inc., White Plains, New York
Wasco Acrylite	Embedded sheets of acrylic plastic	Wasco Products, Inc., Cambridge, Mass.
Wascofilm	Polyethylene moisture barriers in rolls.	Wasco Products, Inc., Cambridge, Mass.
Wascoseal	Plastic sheet vapor barrier.	Wasco Products, Inc., Cambridge, Mass.
Weather-ometer	Testing apparatus, accelerated weathering	Atlas Electric Devices Co., Chicago, Ill.
Weldfast	Thermosetting Cement-Filled epoxy	The Fibercast Corp., Sand Springs, Okla.
Weldox	Adhesives for paint brushes	H. V. Hardman Co., Inc., Belleville, N.J.
Whirlclad	Fused coatings and coating process.	The Polymer Corp., Reading, Penna.
Whirlaint	Coating powders	The Polymer Corp., Reading, Penna.
Wing-Stay	Alkylated phenol antioxidant	The Goodyear Tire and Rubber Co., Akron, Ohio
Witcab	Hydrogenated stearic acid	Witco Chemical Co., New York, New York
Witcoblak	Carbon black	Witco Chemical Co., New York, New York
Witcolith	Carbon black	Witco Chemical Co., New York, New York
Witicizer	Plasticizers	Witco Chemical Co., New York, New York
Wonder Under, The	As backing and/or lamination, padding, cushioning, reinforcing, interfacing medium for all types of vinyl and thermoplastic and thermosetting plastics and rubber.	Pellon Corp., New York, New York
Woodite	Molding material used for molded decorative accessories (syroco and syrocowood).	Syracuse Ornamental Co., Inc., Syracuse, New York
Wyco	Flexible shaft equipment and accessories.	Wyzenbeek and Staff, Inc., Chicago, Ill.
Wilmington Fibre	Vulcanized fibre	Wilmington Fibre Specialty Co., New Castle, Dela.
Wynene	Molded and extruded products.	The National Plastic Products Co., Odenton, Md.
Wynsote	Vinyl Coated Fabric	The Pantasote Co., New York, N.Y.

X

X-1	Plasticizing oil	Neville Chemical Co., Pittsburgh, Penna.
XX	Zinc Oxides	The New Jersey Zinc Co., New York, New York
Xact Ray	Non contact gauges for thickness.	Industrial Gauges, W. Englewood, N.J.
XactRaymatic	Control systems for thickness	Industrial Gauges, W. Englewood, N.J.
Xaloy	Wear resistant ferrous alloy used in bimetallic extruder cylinders.	Industrial Research Laboratories, Div. Honolulu Oil Corp., Los Angeles, Calif.

Z

Zenite	Rubber accelerator	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.
Zenk	Vinyl coatings	Atlas Mineral Products Co., Mertztown, Penna.
Zyrox	Chloride-containing resins and compounds.	Union Carbide and Carbon Corp., New York
Zytel	Nylon Molding Powder	E. I. du Pont de Nemours & Co., Inc., Wilmington, Dela.

ALPHABETICAL LIST OF MANUFACTURERS AND ADDRESSES

A

A & B Plastics, 200 Mercer St., Seattle, 9, Wash.

A & O Plastics Co., 1313 Warren Ave., Downers Grove, Ill.

A & S Steel Rule Die Corp., 195 Chrystie St., New York 2, N.Y.

AAA Plastic Mfg. Co., 308 N. 6th St., St. Louis, Mo.

ABA Tool & Die Co., Inc., 1395 Tolland Tpk., Manchester, Conn.

AGP Corp., 320 W. Main St., Peru, Ind.

A. B. S. Mfg. Co., Inc., 133 W. 19th St., New York, N.Y.

A. S. K. Mfg. Co., 1343 N. Howard St., Philadelphia 22, Pa.

Aacon Industries, Inc., 2303 Coney Island Ave., Brooklyn 23, N.Y.

aaRBee Plastic Co., 4505 W. Jefferson Blvd., Los Angeles 16, Calif.

Aaron Machinery, 45 Crosby, New York, N.Y.

Abaco Industries, 78–21 Queens Blvd., Elmhurst, N.Y.

Abbe Engineering Co., 50 Church St., New York 7, N.Y.

●Abbe, Paul O., Inc., 257 Center Ave., Little Falls, N.J.

Abbott Plastic Machine Corp., 7124 N. Clark St., Chicago 26, Ill.

Able Container Co., 3021 W. 63rd St., Chicago, Ill.

Abco Chemical Co., 2316 Atlantic Ave., Brooklyn 33, N.Y.

Acadia Synthetic Products, 4115 Ogden Ave., Chicago, Ill.

Acco Polymers, 230 W. 41st St., New York 36, N.Y.

Accurate Gold Stamping Co., Inc., 12 W. 17th St., New York 11, N.Y.

Accurate Molding Corp., 35–20 48th Ave., Long Island City 1, N.Y.

Accurate Steel Rule Die Mfg. Co., 22 W. 21st St., New York 10, N.Y.

●Ace Plastic Co., 91–30 Van Wyck Expressway, Jamaica 35, N.Y.

Ace Plastic Molding Corp., 29 E. 19th St., New York 3, N.Y.

Ace Tool & Mfg. Co., 532 Mulberry St., Newark 5, N.J.

Aceto Chemical Co., Inc., 40–40 Lawrence St., Flushing 54, N.Y.

●Acheson Dispersed Pigments Co., 2250 E. Ontario St., Philadelphia 34, Pa.

Acheson Industries, 420 Lexington Ave., New York 17, N.Y.

Achille G. Bureau, Industrial Design 29 W. 57th, N.Y.

Ackerman Plastic Molding Div., Consolidated Iron Steel Mfg. Co., 986 E. 200th St., Cleveland 19, Ohio

●Ackerman-Gould Co., 92–96 Bleecker St., New York 12, N.Y.

Acme Diecutting Mfg. Corp., 43 W. 13th St., New York, N.Y.

Acme Laminating & Plastics Co., Inc., 7207 E. McNichols, Detroit, Mich.

Acme Machinery & Mfg. Co., Inc., 102 Grove St., Worcester 5, Mass.

Acme Plastic Products Co., Inc., 771 Easton Rd., Horsham, Pa.

●Acme Resin Corp., 1401 S. Circle Ave., Forest Park, Ill.

Acme Scientific Co., 1450 W. Randolph, Chicago 7, Ill.

Acor Plasticover Co., Inc., 162 W. 21st St., New York 11, N.Y.

●Acromark Co., The, 5–15 Morrell St., Elizabeth 4, N.J.

Acryvin Corp. of America, 470 E. 99th St., Brooklyn 36, N.Y.

Adams, Kenneth F., 33 Woodycrest Ave., Southbridge, Mass.

Adams Plastic Products, 309 Findlay St., Cincinnati 14, Ohio

●Adamson United Co., 730 Carroll St., Akron 4, Ohio

Adhesive "Plastite" Mastic Co., 114 W. Hubbard St., Chicago 10, Ill.

Adhesive Products Corp., 1660 Boone Ave., New York 60, N.Y.

Adhesive Products, Inc., The, 520 E. Shore Highway, Albany 10, Calif.

Admiral Coated Prods., Inc., 38 Tiffany Place, Bklyn, N.Y.

●Admiral Corp., Molded Products Div., Washington St. & Creamery Rd., W. Chicago, Ill.

Admiral Plastics Corp., 446 12th St., Brooklyn 15, N.Y.

Advance Mfg. Co., 5311 Metropolitan Ave., Brooklyn 37, N.Y.

Advance Molded Plastics Corp., 3124 W. Fillmore St., Chicago 12, Ill.

Advance Molding Corp., 54 W. 21st St., New York 10, N.Y.

●Advance Solvents & Chemical Div. of Carlisle Chemical Works, Inc., 245 5th Ave., New York 16, N.Y.

Aero Plastics Co., 3711 W. Jefferson Blvd., Los Angeles, Calif.

●Aetna Electronics Corp., 207 Stonehinge La., Carle Pl., L.I., N.Y.

●Aetna Engineering Co., Frick Bldg., Pittsburgh 30, Pa.

●Aetna Engineering Co. Div., Hale & Kullgren, Inc., 613 E. Tallmadge Ave., Akron, Ohio

Aetna Plastic Die Co., 7124 W. Toughy Ave., Chicago, Ill.

Agrashall, Inc., 4560 E. 26th St., Los Angeles 22, Calif.

Air Cruisers Co., Div., The Garrett Corp., P.O. Box 180, Belmar, N.J.

Air Reduction Chemical Co., 150 E. 42nd St., New York 17, N.Y.

Airconductors, 1458 W. Compton Blvd., Compton 3, Calif.

Aircraft Die Cutters, 2801 San Fernando Rd., Los Angeles 65, Calif.

Airmate Co., 1150 Nebraska Ave., Toledo 7, Ohio

Airmatic Valve, Inc., 7317 Associate Ave., Cleveland 9, Ohio

Airoyal Co., The, 1990 Springfield Ave., Maplewood, N.J.

Akromold, Inc., 102 W. Wilbeth Rd., Akron 1, Ohio

●Akron Presform Mold Co., The, 2038 Main St., Cuyahoga Falls, Ohio

Aksjeselskapet Ancas, Prinsensgt. 2, Oslo 6, Norway

Al-Be Industries, 6103 Clara St., Bell Garden, Calif.

Albert, L. & Son, Div. of Bellanca Corp., 21 Nottinghamway, Trenton, N. J.

Alcon Plastics, Inc., 17 Simonds Rd., Fitchburg, Mass.

Aldrich Pump Co., The, Foot of Pine, Allentown, Pa.

Alexander Bernard Co. Inc., 15 Moore St., New York, N.Y.

Alexine Corp., 726 Wiehelm St., Harrison, N.J.

Alframine Corp., 72–76 Putnam St., Patterson 4, N.J.

Algemene Kunstzijde Unie N.V., 25 Flint St., Asheville, N.C.

Alkydol Labs., Inc., 3242 S. 50th Ave., Cicero 50, Ill.

All-Power Mfg. Co., 400 Roosevelt Ave., Montebello, Calif.

All Purpose Roll Leaf Corp., 37 W. Century Rd., Paramus, N.J.

All-Tech Industries, Inc., 1850 N.E. 146th St., Miami, Fla.

Alladin Plastics Inc., 5771 W. 96th St., Los Angeles 45, Calif.

Allegheny Ludlum Steel Corp., 2020 Oliver Bldg., Pittsburgh 22, Pa.

Allegheny Plastics, Inc., Rte. 51 & Thorn Run Rd., Coraopolis, Pa.

Allen, Alva F., Clinton, Mo.

Allen Harlander Co., Inc., 385 Gerard Ave., N.Y.

●Allied Chemical & Dye Corp., The Barrett Div., 40 Rector St., New York 6, N.Y.

●Allied Chemical & Dye Corp., General Chemical Div., 40 Rector St., New York 6, N.Y.

●Allied Chemical & Dye Corp., National Aniline Div., 40 Rector St., New York 6, N.Y.

●Allied Chemical & Dye Corp., Nitrogen Div., 40 Rector St., New York 6, N.Y.

●Allied Chemical & Dye Corp., Semet-Solvay Petrochemical Div., 40 Rector St., New York 6, N.Y.

Allied Engravers, Inc., 552 W. Broadway, New York 12, N.Y.

Allied Engraving & Stamping Co., 17–21 Elm St., Buffalo 3, N.Y.

Allied Mfg. Co., 2200 25th Ave., So. Seattle, Wash.

Allied Plasti-Lite Enterprises, Inc., 2712–18 LaSalle St., St. Louis 4, Mo.

Allied Products Corp., 1267 Burt Rd., Detroit 23, Mich.

Allied Resinous Products, Inc., 525 W. Adams St., Conneaut, Ohio

Allied Resins, Inc., Commerce St., Conneaut, Ohio

"Please recommend a material which will . . . "

"Our need is a plastic wheel that . . . "

"Do you know of a manufacturer who . . . ?"

" . . . and how can we insulate it?"

"Who makes stock molded cookie cutters?"

"Where can I purchase a machine that . . . ?"

Each month the Readers' Service Department of MODERN PLASTICS answers scores of questions for our readers. Questions range from simple requests for information about the manufacturer of a stock molded item to requests which must be referred to industry sources for action.

With their extensive files, reference library and wide knowledge of plastics materials, machinery and procedure, the members of the Readers' Service Department can usually supply, or refer you to someone who can supply, the information you want.

If you have a question, feel free to forward it. There is no charge or obligation for this service. Address—Readers' Service Department, MODERN PLASTICS. A complete reply to your inquiry will be sent promptly.
